The fourth logical section, the analytic stage, is concerned with the investigation of the properties of special logical constructions, that is, of classes and correlations of special sorts. The whole of mathematics is included here. So the section is a large one. In fact, it is mathematics, neither more nor less, but it includes an analysis of mathematical ideas not hitherto included in the scope of that science, nor, indeed, contemplated at all. The essence of this stage is construction. It is by means of suitable constructions that the great framework of applied mathematics, comprising the theories of number, quantity, time, and space, is elaborated.

It is impossible, even in brief outline, to explain how mathematics is developed from the concepts of class and correlation, including many-cornered correlations, which are established in the third section. I can only allude to the headings of the process, which is fully developed in the work, _Principia Mathematica_, by Mr. Russell and myself. There are in this process of development seven special sorts of correlations which are of peculiar interest. The first sort comprises one-to-many, many-to-one, and one-to-one correlations. The second sort comprises serial relations, that is, correlations by which the members of some field are arranged in serial order, so that, in the sense defined by the relation, any member of the field is either before or after any other member. The third class comprises inductive relations, that is, correlations on which the theory of mathematical induction depends. The fourth class comprises selective relations, which are required for the general theory of arithmetic operations, and elsewhere. It is in connection with such relations that the famous multiplicative axiom arises for consideration. The fifth class comprises vector relations, from which the theory of quantity arises. The sixth class comprises ratio relations, which interconnect number and quantity. The seventh class comprises three-cornered and four-cornered relations which occur in geometry.

A bare enumeration of technical names, such as the above, is not very illuminating, though it may help to a comprehension of the demarcations of the subject. Please remember that the names are technical names, meant, no doubt, to be suggestive, but used in strictly defined senses. We have suffered much from critics who consider it sufficient to criticise our procedure on the slender basis of a knowledge of the dictionary meanings of such terms. For example, a one-to-one correlation depends on the notion of a class with only one member, and this notion is defined without appeal to the concept of the number one. The notion of diversity is all that is wanted. Thus the class α has only one member, if (1) the class of values of _x_ which satisfies the propositional function,

_x_ is not a member of α,

is not the whole type of relevant values of _x_, and if (2) the propositional function,

_x_ and _y_ are members of α, and _x_ is diverse from _y_

is false, whatever be the values of _x_ and _y_ in the relevant type.

Analogous procedures are obviously possible for higher finite cardinal members. Thus, step by step, the whole cycle of current mathematical ideas is capable of logical definition. The process is detailed and laborious, and, like all science, knows nothing of a royal road of airy phrases. The essence of the process is, first, to construct the notion in terms of the forms of propositions, that is, in terms of the relevant propositional functions, and secondly, to prove the fundamental truths which hold about the notion by reference to the results obtained in the algebraic section of logic.

It will be seen that in this process the whole apparatus of special indefinable mathematical concepts, and special _a priori_ mathematical premises, respecting number, quantity, and space, has vanished. Mathematics is merely an apparatus for analysing the deductions which can be drawn from any particular premises, supplied by commonsense, or by more refined scientific observation, so far as these deductions depend on the forms of the propositions. Propositions of certain forms are continually occurring in thought. Our existing mathematics is the analysis of deductions which concern those forms and in some way are important, either from practical utility or theoretical interest. Here I am speaking of the science as it in fact exists. A theoretical definition of mathematics must include in its scope any deductions depending on the mere forms of propositions. But, of course no one would wish to develop that part of mathematics which in no sense is of importance.

This hasty summary of logical ideas suggests some reflections. The question arises, How many forms of propositions are there? The answer is, An unending number. The reason for the supposed sterility of logical science can thus be discerned. Aristotle

founded the science by conceiving the idea of the form of a proposition, and by conceiving deduction as taking place in virtue of the forms. But he confined propositions to four forms, now named A, I, E, O. So long as logicians were obsessed by this unfortunate restriction, real progress was impossible. Again, in their theory of form, both Aristotle and subsequent logicians came very near to the theory of the logical variable. But to come very near to a true theory, and to grasp its precise application, are two very different things, as the history of science teaches us. Everything of importance has been said before by somebody who did not discover it.

Again, one reason why logical deductions are not obvious is, that logical form is not a subject which ordinarily enters into thought. Commonsense deduction probably moves by blind instinct from concrete proposition to concrete proposition, guided by some habitual association of ideas. Thus commonsense fails in the presence of a wealth of material.

A more important question is the relation of induction, based on observation, to deductive logic. There is a tradition of opposition between adherents of induction and of deduction. In my view, it would be just as sensible for the two ends of a worm to quarrel. Both observation and deduction are necessary for any knowledge worth having. We cannot get at an inductive law without having recourse to a propositional function. For example, take the statement of observed fact,

This body is mercury, and its specific heat is 0·033.

The propositional function is formed,

Either _x_ is not mercury, or its specific heat is 0·033.

The inductive law is the assumption of the truth of the general proposition, that the above propositional function is true for every value of _x_ in the relevant type.

But it is objected that this process and its consequences are so simple that an elaborate science is out of place. In the same way, a British sailor knows the salt sea when he sails over it. What, then, is the use of an elaborate chemical analysis of sea-water? There is the general answer, that you cannot know too much of methods which you always employ; and there is the special answer, that logical forms and logical implications are not so very simple, and that the whole of mathematics is evidence to this effect.

One great use of the study of logical method is not in the region of elaborate deduction, but to guide us in the study of the formation of the main concepts of science. Consider geometry, for example. What are the points which compose space? Euclid tells us that they are without parts and without magnitude. But how is the notion of a point derived from the sense-perceptions from which science starts? Certainly points are not direct deliverances of the senses. Here and there we may see or unpleasantly feel something suggestive of a point. But this is a rare phenomenon, and certainly does not warrant the conception of space as composed of points. Our knowledge of space properties is not based on any observations of relations between points. It arises from experience of relations between bodies. Now a fundamental space-relation between bodies is that one body may be part of another. We are tempted to define the "whole and part" relation by saying that the points occupied by the part are some of the points occupied by the whole. But "whole and part" being more fundamental than the notion of "point," this definition is really circular and vicious.

We accordingly ask whether any other definition of "spatial whole and part" can be given. I think that it can be done in this way, though, if I be mistaken, it is unessential to my general argument. We have come to the conclusion that an extended body is nothing else than the class of perception of it by all its percipients, actual or ideal. Of course, it is not any class of perceptions, but a certain definite sort of class which I have not defined here, except by the vicious method of saying that they are perceptions of body. Now, the perceptions of a part of a body are among the perceptions which compose the whole body. Thus two bodies _a_ and _b_ are both classes of perceptions; and _b_ is part of _a_ when the class which is _b_ is contained in the class which is _a_. It immediately follows from the logical form of this definition that if _b_ is part of _a_, and _c_ is part of _b_, then _c_ is part of _a_. Thus the relation "whole to part" is transitive. Again, it will be convenient to allow that a body is part of itself. This is a mere question of how you draw the definition. With this understanding, the relation is reflexive. Finally, if _a_ is part of _b_, and _b_ is part of _a_, then _a_ and _b_ must be identical. These properties of "whole and part" are not fresh assumptions, they follow from the logical form of our definition.

One assumption has to be made if we assume the ideal infinite divisibility of space. Namely, we assume that every class of perceptions which is an extended body contains other classes of perceptions which are extended bodies diverse from itself. This assumption makes rather a large draft on the theory of ideal perceptions. Geometry vanishes unless in some form you make it. The assumption is not peculiar to my exposition.

It is then possible to define what we mean by a point. A point is the class of extended objects which, in ordinary language, contain that point. The definition, without presupposing the idea of a point, is rather elaborate, and I have not now time for its statement.

The advantage of introducing points into geometry is the simplicity of the logical expression of their mutual relations. For science, simplicity of definition is of slight importance, but simplicity of mutual relations is essential. Another example of this law is the way physicists and chemists have dissolved the simple idea of an extended body, say of a chair, which a child understands, into a bewildering notion of a complex dance of molecules and atoms and electrons and waves of light. They have thereby gained notions with simpler logical relations.

Space as thus conceived is the exact formulation of the properties of the apparent space of the commonsense world of experience. It is not necessarily the best mode of conceiving the space of the physicist. The one essential requisite is that the correspondence between the commonsense world in its space and the physicists' world in its space should be definite and reciprocal.

I will now break off the exposition of the function of logic in connection with the science of natural phenomena. I have endeavoured to exhibit it as the organising principle, analysing the derivation of the concepts from the immediate phenomena, examining the structure of the general propositions which are the assumed laws of nature, establishing their relations to each other in respect to reciprocal implications, deducing the phenomena we may expect under given circumstances.

Logic, properly used, does not shackle thought. It gives freedom, and above all, boldness. Illogical thought hesitates to draw conclusions, because it never knows either what it means, or what it assumes, or how far it trusts its own assumptions, or what will be the effect of any modification of assumptions. Also the mind untrained in that part of constructive logic which is relevant to the subject in hand will be ignorant of the sort of conclusions which follow from various sorts of assumptions, and will be correspondingly dull in divining the inductive laws. The fundamental training in this relevant logic is, undoubtedly, to ponder with an active mind over the known facts of the case, directly observed. But where elaborate deductions are possible, this mental activity requires for its full exercise the direct study of the abstract logical relations. This is applied mathematics.

Neither logic without observation, nor observation without logic, can move one step in the formation of science. We may conceive humanity as engaged in an internecine conflict between youth and age. Youth is not defined by years but by the creative impulse to make something. The aged are those who, before all things, desire not to make a mistake. Logic is the olive branch from the old to the young, the wand which in the hands of youth has the magic property of creating science.

FOOTNOTES:

CHAPTER VII

THE ANATOMY OF SOME SCIENTIFIC IDEAS

I. Fact

THE characteristic of physical science is, that it ignores all judgments of value: for example, æsthetic or moral judgments. It is purely matter-of-fact, and this is the sense in which we must interpret the sonorous phrase, "Man, the servant and the minister of Nature."

The sphere of thought which is thus left is even then too wide for physical science. It would include Ontology, namely, the determination of the nature of what truly exists; in other words, Metaphysics. From an abstract point of view this exclusion of metaphysical inquiry is a pity. Such an inquiry is a necessary critique of the worth of science, to tell us what it all comes to. The reasons for its careful separation from scientific thought are purely practical; namely, because we can agree about science--after due debate--whereas in respect to metaphysics debate has hitherto accentuated disagreement. These characteristics of science and metaphysics were unexpected in the early days of civilised thought. The Greeks thought that metaphysics was easier than physics, and tended to deduce scientific principles from _a priori_ conceptions of the nature of things. They were restrained in this disastrous tendency by their vivid naturalism, their delight in first-hand perception. Mediæval Europe shared the tendency without the restraint. It is possible that some distant generations may arrive at unanimous conclusions on ontological questions, whereas scientific progress may have led to ingrained opposing veins of thought which can neither be reconciled nor abandoned. In such times metaphysics and physical science will exchange their rôles. Meanwhile we must take the case as we find it.

But a problem remains. How can mankind agree about science without a preliminary determination of what really is? The answer must be found in an analysis of the facts which form the field of scientific activity. Mankind perceives, and finds itself thinking about its perceptions. It is the thought that matters and not that element of perception which is not thought. When the immediate judgment has been formed--Hullo, red!--it does not matter if we can imagine that in other circumstances--in better circumstances, perhaps--the judgment would have been--Hullo, blue!--or even--Hullo, nothing! For all intents and purposes, at the time it was red. Everything else is hypothetical reconstruction. The field of physical science is composed of these primary thoughts, and of thoughts about these thoughts.

But--to avoid confusion--a false simplicity has been introduced above into the example given of a primary perceptive thought. "Hullo, red!" is not really a primary perceptive thought, though it often is the first thought which finds verbal expression even silently in the mind. Nothing is in isolation. The perception of red is of a red object in its relations to the whole content of the perceiving consciousness.

Among the most easily analysed of such relations are the space relations. Again the red object is in immediate perception nothing else than a red object. It is better termed an "object of redness." Thus a better approximation to an immediate perceptive judgment is, "Hullo, object of redness there!" But, of course, in this formulation other more complex relations are omitted.

This tendency towards a false simplicity in scientific analysis, to an excessive abstraction, to an over-universalising of universals, is derived from the earlier metaphysical stage. It arises from the implicit belief that we are endeavouring to qualify the real with appropriate adjectives. In conformity with this tendency we think, "this real thing is red." Whereas our true goal is to make explicit our perception of the apparent in terms of its relations. What we perceive is redness related to other apparents. Our object is the analysis of the relations.

One aim of science is the harmony of thought, that is, to secure that judgments which are logical contraries should not be thought-expressions of consciousness. Another aim is the extension of such harmonised thought.

Some thoughts arise directly from sense-presentation, and are part of the state of consciousness which is perception. Such a thought is, "An object of redness is there." But in general the thought is not verbal, but is a direct apprehension of qualities and relations within the content of consciousness.

Amid such thoughts there can be no lack of harmony. For direct apprehension is in its essence unique, and it is impossible to apprehend an object as both red and blue. Subsequently it may be judged that if other elements of the consciousness had been different, the apprehension would have been of a blue object. Then--under certain circumstances--the original apprehension will be called an error. But for all that the fact remains, there was an apprehension of a red object.

When we speak of sense-presentation, we mean these primary thoughts essentially involved in its perception. But there are thoughts about thoughts, and thoughts derived from other thoughts. These are secondary thoughts. At this point it is well explicitly to discriminate between an actual thought-expression, namely, a judgment actually made, and a mere proposition which is a hypothetical thought-expression, namely, an imagined possibility of thought-expression. Note that the actual complete thought-content of the consciousness is explicitly neither affirmed or denied. It is just what _is_ thought. Thus, to think "two and two make four" is distinct from affirming that two and two make four. In the first case the proposition is the thought-expression, in the second case the affirmation of the proposition is the thought-expression, and the proposition has been degraded to a mere proposition, namely, to a hypothetical thought-expression which is reflected upon.

A distinction is sometimes made between facts and thoughts. So far as physical science is concerned, the facts are thoughts, and thoughts are facts. Namely, the facts of sense-presentation as they affect science are those elements in the immediate apprehensions which are thoughts. Also, actual thought-expressions, primary or secondary, are the material facts which science interprets.

The distinction that facts are given, but thoughts are free, is not absolute. We can select and modify our sense-presentation, so that facts--in the narrower sense of immediate apprehension of sense-presentation--are to some degree subject to volition. Again, our stream of thought-expression is only partially modified by explicit volition. We can choose our physical experience, and we find ourselves thinking; namely, on the one hand there is selection amid the dominant necessity of sense, and on the other hand, the thought-content of consciousness (so far as secondary thoughts are concerned) is not wholly constituted by the selection of will.

Thus, on the whole there is a large primary region of secondary thought, as well as of the primary thoughts of sense-presentation, which is given in type. That is the way in which we do think of things, not wholly from any abstract necessity, so far as we know, but because we have inherited the method from an environment. It is the way we find ourselves thinking, a way which can only be fundamentally laid aside by an immense effort, and then only for isolated short periods of time. This is what I have called the "whole apparatus of commonsense thought."

It is this body of thought which is assumed in science. It is a way of thinking rather than a set of axioms. It is, in fact, the set of concepts which commonsense has found useful in sorting out human experience. It is modified in detail, but assumed in gross. The explanations of science are directed to finding conceptions and propositions concerning nature which explain the importance of these common sense notions. For example, a chair is a common sense notion, molecules and electrons explain our vision of chairs.

Now science aims at harmonising our reflective and derivative thoughts with the primary thoughts involved in the immediate apprehension of sense-presentation. It also aims at producing such derivative thoughts, logically knit together. This is scientific theory; and the harmony to be achieved is the agreement of theory with observation, which is the apprehension of sense-presentation.

Thus there is a twofold scientific aim: (1) the production of theory which agrees with experience; and (2) the explanation of commonsense concepts of nature, at least in their main outlines. This explanation consists in the preservation of the concepts in a scientific theory of harmonised thought.

It is not asserted that this is what scientists in the past meant to achieve, or thought that they could achieve. It is suggested as the actual result of scientific effort, so far as that effort has had any measure of success. In short, we are here discussing the natural history of ideas and not volitions of scientists.

II. Objects

We perceive things in space. For example, among such things are dogs, chairs, curtains, drops of water, gusts of air, flames, rainbows, chimes of bells, odours, aches and pains. There is a scientific explanation of the origin of these perceptions. This explanation is given in terms of molecules, atoms, electrons, and their mutual relations, in particular of their space-relations, and waves of disturbance of these space-relations which are propagated through space. The primary elements of the scientific explanation--molecules, etc.--are not the things directly perceived. For example, we do not perceive a wave of light; the sensation of sight is the resultant effect of the impact of millions of such waves through a stretch of time. Thus the object directly perceived corresponds to a series of events in the physical world, events which are prolonged through a stretch of time. Nor is it true that a perceived object always corresponds to the same group of molecules. After a few years we recognise the same cat, but we are thereby related to different molecules.

Again, neglecting for a moment the scientific explanation, the perceived object is largely the supposition of our imagination. When we recognised the cat, we also recognised that it was glad to see us. But we merely heard its mewing, saw it arch its back, and felt it rubbing itself against us. We must distinguish, therefore, between the many direct objects of sense, and the single indirect object of thought which is the cat.

Thus, when we say that we perceived the cat and understood its feelings, we mean that we heard a sense-object of sound, that we saw a sense-object of sight, that we felt a sense-object of touch, and that we thought of a cat and imagined its feelings.

Sense-objects are correlated by time-relations and space-relations. Three simultaneous sense-objects which are also spatially coincident, are combined by thought into the perception of one cat. Such combination of sense-objects is an instinctive immediate judgment in general without effort of reasoning. Sometimes only one sense-object is present. For example, we hear mewing and say there must be a cat in the room. The transition from the sense-object to the cat has then been made, by deliberate ratiocination. Even the concurrence of sense-objects may provoke such a self-conscious effort. For example, in the dark we feel something, and hear mewing from the same place, and think, Surely this is a cat. Sight is more bold; when we see a cat, we do not think further. We identify the sight with the cat, whereas the cat and the mew are separate. But such immediate identification of a sight object and an object of thought may lead to error; the birds pecked at the grapes of Apelles.

A single sense-object is a complex entity. The sight-object of a tile on the hearth may remain unchanged as we watch it in a steady light, remaining ourselves unchanged in position. Even then it is prolonged in time, and has parts in space. Also it is somewhat

arbitrarily distinguished from a larger whole of which it forms part. But the glancing fire-light and a change in our position alters the sight-object. We judge that the tile thought-object remains unchanged. The sight-object of the coal on the fire gradually modifies, though within short intervals it remains unchanged. We judge that the coal thought-object is changing. The flame is never the same, and its shape is only vaguely distinguishable.

We conclude that a single self-identical sight-object is already a phantasy of thought. Consider the unchanging sight-object of the tile, as we remain still in a steady light. Now a sense-object perceived at one time is a distinct object from a sense-object seen at another time. Thus the sight of the tile at noon is distinct from its sight at 12.30. But there is no such thing as a sense-object at an instant. As we stare at the tile, a minute, or a second, or a tenth of a second, has flown by: essentially there is a duration. There is a stream of sight, and we can distinguish its parts. But the parts also are streams, and it is only in thought that the stream separates into a succession of elements. The stream may be "steady" as in the case of the unchanging sight-tile, or may be "turbulent" as in the case of the glancing sight-flame. In either case a sight-object is some arbitrarily small part of the stream.

Again, the stream which forms the succession of sight-tiles is merely a distinguishable part of the whole stream of sight-presentation.

So, finally, we conceive ourselves each experiencing a complete time-flux (or stream) of sense-presentation. This stream is distinguishable into parts. The grounds of distinction are differences of sense--including within that term, differences of types of sense, and differences of quality and of intensity within the same type of sense--and differences of time-relations, and differences of space-relations. Also the parts are not mutually exclusive and exist in unbounded variety.

The time-relation between the parts raises the questions of memory and recognition, subjects too complex for discussion here. One remark must be made. If it be admitted, as stated above, that we live in durations and not in instants, namely, that the present essentially occupies a stretch of time, the distinction between memory and immediate presentation cannot be quite fundamental; for always we have with us the fading present as it becomes the immediate past. This region of our consciousness is neither pure memory nor pure immediate presentation. Anyhow, memory is also a presentation in consciousness.

Another point is to be noted in connection with memory. There is no directly perceived time-relation between a present event and a past event. The present event is only related to the memory of the past event. But the memory of a past event is itself a present element in consciousness. We assert the principle that directly perceived relations can only exist between elements of consciousness, both in that present during which the perception occurs. All other relations between elements of perception are inferential constructions. It thus becomes necessary to explain how the time stream of events establishes itself in thought, and how the apparent world fails to collapse into one single present. The solution of the difficulty is arrived at by observing that the present is itself a duration, and therefore includes directly perceived time-relations between events contained within it. In other words we put the present on the same footing as the past and the future in respect to the inclusion within it of antecedent and succeeding events, so that past, present, and future are in this respect exactly analogous ideas. Thus there will be two events _a_ and _b_, both in the same present, but the event _a_ will be directly perceived to precede the event _b_. Again time flows on, and the event _a_ fades into the past, and in the new present duration events _b_ and _c_ occur, event _b_ preceding event _c_, also in the same present duration there is the memory of the time-relation between _a_ and _b_. Then by an inferential construction the event _a_ in the past precedes the event _c_ in the present. By proceeding according to this principle the time-relations between elements of consciousness, not in the same present, are established. The method of procedure here explained is a first example of what we will call the Principle of Aggregation. This is one of the fundamental principles of mental construction according to which our conception of the external physical world is constructed. Other examples will later on be met with.

The space-relations between the parts are confused and fluctuating, and in general lack determinate precision. The master-key by which we confine our attention to such parts as possess mutual relations sufficiently simple for our intellects to consider is the principle of convergence to simplicity with diminution of extent. We will call it the "principle of convergence." This principle extends throughout the whole field of sense-presentation.

The first application of the principle occurs in respect to time. The shorter the stretch of time, the simpler are the aspects of the sense-presentation contained within it. The perplexing effects of change are diminished and in many cases can be neglected. Nature has restricted the acts of thought which endeavour to realise the content of the present, to stretches of time sufficiently short to secure this static simplicity over the greater part of the sense-stream.

Spatial relations become simplified within the approximately static sense-world of the short time. A further simplicity is gained by partitioning this static world into parts of restricted space-content. The various parts thus obtained have simpler mutual space-relations, and again the principle of convergence holds.

Finally, the last simplicity is obtained by partitioning the parts, already restricted as to space and time, into further parts characterised by homogeneity in type of sense, and homogeneity in quality and intensity of sense. These three processes of restriction yield, finally, the sense-objects which have been mentioned above. Thus the sense-object is the result of an active process of discrimination made in virtue of the principle of convergence. It is the result of the quest for simplicity of relations within the complete stream of sense-presentation.

The thought-objects of perception are instances of a fundamental law of nature, the law of objective stability. It is the law of the coherence of sense-objects. This law of stability has an application to time and an application to space; also it must be applied in conjunction with that other law, the principle of convergence to simplicity from which sense-objects are derived.

Some composite partial streams of sense-presentation can be distinguished with the following characteristics: (1) the time-succession of sense-objects, belonging to a single sense, involved in any such a composite partial stream, is composed of very similar objects whose modifications increase only gradually, and thus forms a homogeneous component stream within the composite stream; (2) the space-relations of those sense-objects (of various senses) of such a composite stream which are confined within any sufficiently short time are identical so far as they are definitely apprehended, and thus these various component streams, each homogeneous, "cohere" to form the whole composite partial stream; (3) there are other sense-presentations occurring in association with that composite partial stream which can be determined by rules derived from analogous composite partial streams, with other space and time relations, provided that the analogy be sufficiently close. Call these the "associated sense-presentations." A partial stream of this sort, viewed as a whole, is here called a "first crude thought-object of perception."

For example, we look at an orange for half a minute, handle it, and smell it, note its position in the fruit-basket, and then turn away. The stream of sense-presentation of the orange during that half-minute is a first crude thought-object of perception. Among the associated sense presentations are those of the fruit-basket which we conceive as supporting the orange.

The essential ground of the association of sense-objects of various types, perceived within one short duration, into a first crude thought-object of perception is the coincidence of their space-relations, that is, in general an approximate coincidence of such relations perhaps only vaguely apprehended. Thus coincident space-relations associate sense-objects into a first crude thought-object, and diverse space-relations dissociate sense-objects from aggregation into a first crude thought-object. In respect to some groups of sense-objects the association may be an immediate judgment devoid of all inference, so that the primary perceptual thought is that of the first crude thought-object, and the separate sense-objects are the result of reflective analysis acting on memory. For example sense-objects of sight and sense-objects of touch are often thus primarily associated and only secondarily dissociated in thought. But sometimes the association is wavering and indeterminate, for example, that between the sound-object of the mew of the cat and the sight-object of the cat. Thus to sum up, the partial stream of sense-perceptions coalesces into that first crude thought-object of perception which is the momentary cat because the sense-perceptions belonging to this stream are in the same place, but equally it would be true to say that they are in the same place because they belong to the same momentary cat. This analysis of the complete stream of sense-presentation in any small present duration into a variety of first crude thought-objects only partially fits the facts; for one reason because many sense-objects, such as sound for instance, have vague and indeterminate space-relations, for example vaguely those space-relations which we associate with our organs of sense and also vaguely those of the origin from which (in the scientific explanation) they proceed.

The procedure by which the orange of half a minute is elaborated into the orange in the ordinary sense of the term involves in addition the two principles of aggregation and of hypothetical sense-presentation.

The principle of aggregation, as here employed, takes the form that many distinct first crude thought-objects of perception are conceived as one thought-object of perception, if the many partial streams forming these objects are sufficiently analogous, if their times of occurrence are distinct, and if the associated sense-presentations are sufficiently analogous.

For example, after leaving the orange, in five minutes we return. A new first crude thought-object of perception presents itself to us, indistinguishable from the half-minute orange we previously experienced; it is in the same fruit-basket. We aggregate the two presentations of an orange into the same orange. By such aggregations we obtain "second crude thought-objects of perception." But however far we can proceed with aggregation of this type, the orange is more than that. For example, what do we mean when

we say, The orange is in the cupboard, if Tom has not eaten it?

The world of present fact is more than a stream of sense-presentation. We find ourselves with emotions, volitions, imaginations, conceptions, and judgments. No factor which enters into consciousness is by itself or even can exist in isolation. We are analysing certain relations between sense-presentation and other factors of consciousness. Hitherto we have taken into account merely the factors of concept and judgment. Imagination is necessary to complete the orange, namely, the imagination of hypothetical sense-presentations. It is beside the point to argue whether we ought to have such imaginations, or to discuss what are the metaphysical truths concerning reality to which they correspond. We are here only concerned with the fact that such imaginations exist and essentially enter into the formation of the concepts of the thought-objects of perception which are the first data of science. We conceive the orange as a permanent collection of sense-presentations existing as if they were an actual element in our consciousness, which they are not. The orange is thus conceived as in the cupboard with its shape, odour, colour, and other qualities. Namely, we imagine hypothetical possibilities of sense-presentation, and conceive their want of actuality in our consciousness as immaterial to their existence in fact. The fact which is essential for science is our conception; its meaning in regard to the metaphysics of reality is of no scientific importance, so far as physical science is concerned.

The orange completed in this way is the thought-object of perception.

It must be remembered that the judgments and concepts arising in the formation of thought-objects of perception are in the main instinctive judgments, and instinctive concepts, and are not concepts and judgments consciously sought for and consciously criticised before adoption. Their adoption is facilitated by and interwoven with the expectation of the future in which the hypothetical passes into the actual, and also with the further judgment of the existence of other consciousnesses, so that much that is hypothetical to one consciousness is judged to be actual to others.

The thought-object of perception is, in fact, a device to make plain to our reflective consciousness relations which hold within the complete stream of sense-presentation. Concerning the utility of this weapon there can be no question; it is the rock upon which the whole structure of commonsense thought is erected. But when we consider the limits of its application the evidence is confused. A great part of our sense-presentation can be construed as perception of various persistent thought-objects. But hardly at any time can the sense-presentations be construed wholly in that way. Sights lend themselves easily to this construction, but sight can be baffled: for example, consider reflections in looking-glasses, apparently bent sticks half in and half out of water, rainbows, brilliant patches of light which conceal the object from which they emanate, and many analogous phenomena. Sound is more difficult; it tends largely to disengage itself from any such object. For example, we see the bell, but we hear the sound which comes from the bell; yet we also say that we hear the bell. Again, a toothache is largely by itself, and is only indirectly a perception of the nerve of the tooth. Illustrations to the same effect can be accumulated from every type of sensation.

Another difficulty arises from the fact of change. The thought-object is conceived as one thing, wholly actual at each instant. But since the meat has been bought it has been cooked, the grass grows and then withers, the coal burns in the fire, the pyramids of Egypt remain unchanged for ages, but even the pyramids are not wholly unchanged. The difficulty of change is merely evaded by affixing a technical Latin name to a supposed logical fallacy. A slight cooking leaves the meat the same object, but two days in the oven burns it to a cinder. When does the meat cease to be? Now the chief use of the thought-object is the concept of it as one thing, here and now, which later can be recognised, there and then. This concept applies sufficiently well to most things for short times, and to many things for long times. But sense-presentation as a whole entirely refuses to be patient of the concept.

We have now come to the reflective region of explanation, which is science.

A great part of the difficulty is at once removed by applying the principle of convergence to simplicity. We habitually make our thought-objects too large; we should think in smaller parts. For example, the Sphinx has changed by its nose becoming chipped, but by proper inquiry we could find the missing part in some private house of Western Europe or Northern America. Thus, either part, the rest of the Sphinx or the chip, regains its permanence. Furthermore, we enlarge this explanation by conceiving parts so small that they can only be observed under the most favourable circumstances. This is a wide extension of the principle of convergence in its application to nature; but it is a principle amply supported by the history of exact observation.

Thus, change in thought-objects of perception is largely explained as a disintegration into smaller parts, themselves thought-objects of perception. The thought-objects of perception which are presupposed in the common thought of civilised beings are almost wholly hypothetical. The material universe is largely a concept of the imagination which rests on a slender basis of direct sense-presentation. But none the less it is a fact; for it is a fact that actually we imagine it. Thus it is actual in our consciousness just

as sense-presentation also is actual there. The effort of reflective criticism is to make these two factors in our consciousness agree where they are related, namely, to construe our sense-presentation as actual realisation of the hypothetical thought-objects of perception.

The wholesale employment of purely hypothetical thought-objects of perception enables science to explain some of the stray sense-objects which cannot be construed as perceptions of a thought-object of perception: for example, sounds. But the phenomena as a whole defy explanation on these lines until a further fundamental step is taken, which transforms the whole concept of the material universe. Namely, the thought-object of perception is superseded by the thought-object of science.

The thought-objects of science are molecules, atoms, and electrons. The peculiarity of these objects is that they have shed all the qualities which are capable of direct sense-representation in consciousness. They are known to us only by their associated phenomena, namely, series of events in which they are implicated are represented in our consciousness by sense-presentations. In this way, the thought-objects of science are conceived as the causes of sense-representation. The transition from thought-objects of perception to thought-objects of science is decently veiled by an elaborate theory concerning primary and secondary qualities of bodies.

This device, by which sense-presentations are represented in thought as our perception of events in which thought-objects of science are implicated, is the fundamental means by which a bridge is formed between the fluid vagueness of sense and the exact definition of thought. In thought a proposition is either true or false, an entity is exactly what it is, and relations between entities are expressible (in idea) by definite propositions about distinctly conceived entities. Sense-perception knows none of these things, except by courtesy. Accuracy essentially collapses at some stage of inquiry.

III. Time and Space

Recapitulation.--Relations of time and relations of space hold between sense-objects of perception. These sense-objects are distinguished as separate objects by the recognition of either (1) differences of sense-content, or (2) time-relations between them other than simultaneity, or (3) space-relations between them other than coincidence. Thus sense-objects arise from the recognition of contrast within the complete stream of sense-presentation, namely, from the recognition of the objects as related terms, by relations which contrast them. Differences of sense-content are infinitely complex in their variety. Their analysis under the heading of general ideas is the unending task of physical science. Time-relations and space-relations are comparatively simple, and the general ideas according to which their analysis should proceed are obvious.

This simplicity of time and space is perhaps the reason why thought chooses them as the permanent ground for objectival distinction, throwing the various sense-objects thus obtainable into one heap, as a first crude thought-object of perception, and thence, as described above, obtaining a thought-object of perception. Thus a thought-object of perception conceived as in the present of a short duration is a first crude thought-object of perception either actual or hypothetical. Such a thought-object of perception, confined within a short duration, takes on the space-relations of its component sense-objects within that same duration. Accordingly thought-objects of perception, conceived in their whole extents, have to each other the time-relationships of their complete existences, and within any small duration have to each other the space-relationships of their component sense-objects which lie within that duration.

Relations bind together: thus thought-objects of perception are connected in time and in space. The genesis of the objectival analysis of sense-presentation is the recognition of sense-objects as distinct terms in time-relations and space-relations: thus thought-objects of perception are separated by time and by space.

Whole and Part.--A sense-object is part of the complete stream of presentation. This concept of being a part is merely the statement of the relation of the sense-object to the complete sense-presentation for that consciousness. Also a sense-object can be part of another sense-object. It can be a part in two ways, namely, a part in time and a part in space. It seems probable that both these concepts of time-part and space-part are fundamental; that is, are concepts expressing relations which are directly presented to us, and are not concepts about concepts. In that case no further definition of the actual presentation is possible. It may even then be possible to define an adequate criterion of the occurrence of such a presentation. For example, adopting for the moment a realist metaphysic as to the existence of the physical world of molecules and electrons, the vision of a chair as occurring for some definite person at some definite time is essentially indefinable. It is his vision, though each of us guesses that it must be uncommonly like our vision under analogous circumstances. But the existence of the definable molecules and waves of light in certain definable relations to his bodily organs of sense, his body also being in a certain definable state, forms an adequate criterion

of the occurrence of the vision, a criterion which is accepted in Courts of Law and for physical science is tacitly substituted for the vision.

The connection between the relations "whole and part" and "all and some" is intimate. It can be explained thus so far as concerns directly presented sense-objects. Call two sense-objects "separated" if there is no third sense-object which is a part of both of them. Then an object A is composed of the two objects B and C, if (1) B and C are both parts of A, (2) B and C are separated, and (3) there is no part of A which is separated both from B and from C. In such a case the class α which is composed of the two objects B and C is often substituted in thought for the sense-object A. But this process presupposes the fundamental relation "whole and part." Conversely the objects B and C may be actual sense-objects, but the sense-object A which corresponds to the class α may remain hypothetical. For example, the round world on which we live remains a conception corresponding to no single sense-object at any time presented in any human being's consciousness.

It is possible, however, that some mode of conceiving the whole-and-part relation between extended objects as the all-and-some relation of logical classes can be found. But in this case the extended objects as here conceived cannot be the true sense-objects which are present to consciousness. For as here conceived a part of a sense-object is another sense-object of the same type; and therefore one sense-object cannot be a class of other sense-objects, just as a tea-spoon cannot be a class of other tea-spoons. The ordinary way in thought by which whole-and-part is reduced to all-and-some is by the device of points, namely, the part of an object occupies some of the points occupied by the whole object. If any one holds that in his consciousness the sense-presentation is a presentation of point-objects, and that an extended object is merely a class of such point-objects collected together in thought, then this ordinary method is completely satisfactory. We shall proceed on the assumption that this conception of directly perceived point-objects has no relation to the facts.

In the preceding address on "The Organisation of Thought," another mode is suggested. But this method would apply only to the thought-object of perception, and has no reference to the primary sense-objects here considered. Accordingly it must reckon as a subordinate device for a later stage of thought.

Thus the point-object in time and the point-object in space, and the double point-object both in time and space, must be conceived as intellectual constructions. The fundamental fact is the sense-object, extended both in time and space, with the fundamental relation of whole-to-part to other such objects, and subject to the law of convergence to simplicity as we proceed in thought through a series of successively contained parts.

The relation whole-to-part is a temporal or spatial relation, and is therefore primarily a relation holding between sense-objects of perception, and it is only derivatively ascribed to the thought-objects of perception of which they are components. More generally, space and time relations hold primarily between sense-objects of perception and derivatively between thought-objects of perception.

Definition of Points.--The genesis of points of time and of space can now be studied. We must distinguish (1) sense-time and sense-space, and (2) thought-time of perception and thought-space of perception.

Sense-time and sense-space are the actually observed time-relations and space-relations between sense-objects. Sense-time and sense-space have no points except, perhaps, a few sparse instances, sufficient to suggest the logical idea; also, sense-time and sense-space are discontinuous and fragmentary.

Thought-time of perception and thought-space of perception are the time and space relations which hold between thought-objects of perception. Thought-time of perception and thought-space of perception are each continuous. By "continuous" is here meant that all thought-objects of perception have to each other a time (or space) relation.

The origin of points is the effort to take full advantage of the principle of convergence to simplicity. In so far as this principle does not apply, a point is merely a cumbrous way of directing attention to a set of relations between a certain set of thought-objects of perception, which set of relations, though actual so far as a thought-object is actual, is (under this supposition) of no particular importance. Thus the proved importance in physical science of the concepts of points in time and points in space is a tribute to the wide applicability of this principle of convergence.

Euclid defines a point as without parts and without magnitude. In modern language a point is often described as an ideal limit by indefinitely continuing the process of diminishing a volume (or area). Points as thus conceived are often called convenient fictions. This language is ambiguous. What is meant by a fiction? If it means a conception which does not correspond to any fact, there is

some difficulty in understanding how it can be of any use in physical science. For example, the fiction of a red man in a green coat inhabiting the moon can never be of the slightest scientific service, simply because--as we may presume--it corresponds to no fact. By calling the concept of points a convenient fiction, it must be meant that the concept does correspond to some important facts. It is, then, requisite, in the place of such vague allusiveness, to explain exactly what are the facts to which the concept corresponds.

We are not much helped by explaining that a point is an ideal limit. What is a limit? The idea of a limit has a precise meaning in the theory of series, and in the theory of the values of functions; but neither of these meanings apply here. It may be observed that, before the ordinary mathematical meanings of limit had received a precise explanation, the idea of a point as a limit might be considered as one among other examples of an idea only to be apprehended by direct intuition. This view is not now open to us. Thus, again, we are confronted with the question: What are the precise properties meant when a point is described as an ideal limit? The discussion which now follows is an attempt to express the concept of a point in terms of thought-objects of perception related together by the whole-and-part relation, considered either as a time-relation or as a space-relation. If it is so preferred, it may be considered that the discussion is directed towards a precise elucidation of the term "ideal limit" as often used in this connection.

The subsequent explanations can be made easier to follow by a small piece of symbolism: Let _aEb_ mean that "_b_ is part of _a_." We need not decide whether we are talking of time-parts or space-parts, but whichever choice is supposed to be made must be conceived as adhered to throughout any connected discussion. The symbol _E_ may be considered as the initial letter of "encloses," so we read "_aEb_" as "_a_ encloses _b_." Again the "field of _E_" is the set of things which either enclose or are enclosed, _i. e._ everything "_a_," which is such that _x_ can be found so that either _aEx_ or _xEa_. A member of the field of _E_ is called "an enclosure-object."

Now, we assume that this relation of whole-to-part, which in the future we will call "enclosure," always satisfies the conditions in that the relation _E_ is (1) transitive, (2) asymmetrical, and (3) with its domain including its converse domain.

These four conditions deserve some slight consideration; only the first two of them embody hypotheses which enter vitally into the reasoning.

Condition (1) may be stated as the condition that _aEb_ and _bEc_ always implies _aEc_. The fact that an entity _b_ can be found such that _aEb_ and _bEc_ may be conceived as a relation between _a_ and _c_. It is natural to write _E_^2 for this relation. Thus the condition is now written: If _aE_^2_c_, then _aEc_. This can be still otherwise expressed by saying that the relation _E_^2 implies, whenever it holds, that the relation _E_ also holds.

Condition (2) is partly a mere question of trivial definition, and partly a substantial assumption. The asymmetrical relation (_E_) is such that _aEb_ and _bEa_ can never hold simultaneously. This property splits up into two parts: (1) that no instance of _aEb_ and _bEa_ and "_a_ diverse from _b_," can occur, and (2) that _aEa_ cannot occur. The first part is a substantial assumption, the second part (so far as we are concerned) reduces to the trivial convention that we shall not consider an object as part of itself, but will confine attention to "proper parts."

Condition (3) means that _aEb_ always implies that _c_ can be found such that _bEc_. This condition, taken in conjunction with the fact that we are only considering proper parts, is the assertion of the principle of the indefinite divisibility of extended objects, both in space and in time.

An indivisible part will lack duration in time, and extension in space, and is thus an entity of essentially a different character to a divisible part. If we admit such indivisibles as the only true sense-objects, our subsequent procedure is an unnecessary elaboration.

It will be found that a fourth condition is necessary owing to logical difficulties connected with the theory of an infinite number of choices. It will not be necessary for us to enter further on this question, which involves difficult considerations of abstract logic. The outcome is, that apart from hypothesis we cannot prove the existence of the sets, each containing an infinite number of objects, which are here called points, as will be explained immediately.

Now consider a set of enclosure objects which is such that (1) of any two of its members one encloses the other, and (2) there is no member which is enclosed by all the others, and (3) there is no enclosure-object, not a member of the set which is enclosed by every member of the set. Call such a set a "convergent set of enclosure-objects." As we pass along the series from larger to smaller members, evidently we converge towards an ideal simplicity to any degree of approximation to which we like to proceed, and the series as a whole embodies the complete ideal along that route of approximation. In fact, to repeat, the series is a _route of

approximation_.

We have now to inquire if the principle of convergence to simplicity may be expected to yield the same type of simplicity for every such convergent route. The answer is, as we might expect, namely, that this depends upon the nature of the properties which are to be simplified.

For example, consider the application to time. Now, time is one-dimensional; so when this property of one-dimensionality has been expressed by the proper conditions, not here stated, a convergent set of enclosure-objects must, considered as a route of approximation, exhibit the properties of one unique instant of time, as ordinarily conceived by the euclidean definition. Accordingly, whatever simplicity is to be achieved by the application to time of the principle of convergence to simplicity must be exhibited among the properties of any such route of approximation.

For space, different considerations arise. Owing to its multiple dimensions, we can show that different convergent sets of enclosure-objects, indicating different routes of approximation, may exhibit convergence to different types of simplicity, some more complex than others.

For example, consider a rectangular box of height _h_ ft., breadth _b_ ft., and thickness _c_ ft. Now, keep _h_ and _b_ constant, and let the central plane (height _h_, breadth _b_) perpendicular to the thickness be fixed, then make _c_ diminish indefinitely. We thus obtain a convergent series of an indefinitely large number of boxes, and there is no smallest box. Thus this convergent series exhibits the route of approximation towards the type of simplicity expressed as being a plane area of height _h_, breadth _b_, and no thickness.

Again, by keeping the central line of height _h_ fixed, and by making _b_ and _c_ diminish indefinitely, the series converges to the segment of a straight line of length _h_.

Finally, by keeping only the central point fixed, and by making _h_, _b_, and _c_ diminish indefinitely, the series converges to a point.

Furthermore, we have introduced as yet no concept which would prevent an enclosure-object being formed of detached fragments in space. Thus we can easily imagine a convergent set which converges to a number of points in space. For example, each object of the set might be formed of two not overlapping spheres of radius _r_, with centres _A_ and _B_. Then by diminishing _r_ indefinitely, and keeping _A_ and _B_ fixed, we have convergence to the pair of points _A_ and _B_.

It remains now to consider how those convergent sets which converge to a single point can be discriminated from all the other types of such sets, merely by utilising concepts founded on the relation of enclosure.

Let us name convergent sets by Greek letters; by proceeding "forward" along any such set let us understand the process of continually passing from the larger to the smaller enclosure-objects which form the set.

The convergent set α will be said to "cover" the convergent set β, if every member of α encloses some members of β. We notice that if an enclosure-object _x_ encloses any member (_y_) of β, then every member of the "tail-end" of β, found by proceeding forward along β from _y_, must be enclosed by _x_. Thus if α covers β, every member of α encloses every member of the tail-end of β, starting from the largest member of β which is enclosed by that member of α.

It is possible for each of two convergent sets to cover the other. For example, let one set (α) be a set of concentric spheres converging to their centre _A_, and the other set (β) be a set of concentric cubes, similarly situated, converging to the same centre _A_. Then α and β will each cover the other.

Let two convergent sets which are such that each covers the other be called "equal."

Then it is a sufficient condition to secure that a convergent set α possesses the point type of convergence, if every convergent set covered by it is also equal to it, namely, α is a convergent set with the punctual type of convergence, if "α covers β" always implies that β covers α.

It can easily be seen by simple examples that the other types of convergence to surfaces or lines or sets of points cannot possess this property. Consider, for example, the three convergent sets of boxes in the preceding illustration, which converge respectively to a central plane, a central line in the central plane, and the central point in the central line. The first set covers the second and third sets, and the second set covers the third set, but no two of the sets are equal.

It is a more difficult question to determine whether the condition here indicated as sufficient to secure the punctual type of convergence is also necessary. The question turns on how far thought-objects of perception possess exact boundaries prior to the elaboration of exact mathematical concepts of space. If they are to be conceived as possessing such exact boundaries, then convergent sets converging to points on such boundaries must be allowed for. The procedure necessary for the specification of the complete punctual condition becomes then very elaborate,[3] and will not be considered here.

But such exact determination as is involved in the conception of an exact spatial boundary does not seem to belong to the true thought-object of perception. The ascription of an exact boundary really belongs to the transition stage of thought as it passes from the thought-object of perception to the thought-object of science. The transition from the sense-object immediately presented to the thought-object of perception is historically made in a wavering indeterminate line of thought. The definite stages here marked out simply serve to prove that a logically explicable transition is possible.

We accordingly assume that the condition laid down above to secure the punctual convergence of a convergent set of enclosure-objects is not only sufficient, but necessary.

It can be proved that, if two convergent sets of enclosure-objects are both equal to a third convergent set, they are equal to each other. Consider now any punctual convergent set (α). We want to define the "point" to which α is a route of approximation in a way which is neutral between α and all the convergent sets which are equal to α. Each of these sets is a route of approximation to the same "point" as α. This definition is secured if we define the point as the class formed by all the enclosure-objects which belong either to α or to any convergent set which is equal to α. Let _P_ be this class of enclosure-objects. Then any convergent set (β) which consists of enclosure-objects entirely selected from members of the class _P_ must be a route of approximation to the same "point" as does the original punctual set α; namely, provided that we choose a small enough enclosure-object in β, we can always find a member of α which encloses it; and provided that we choose a small enough enclosure-object in α, we can always find a member of β which encloses it. Thus _P_ only includes convergent sets of the punctual type, and the route of approximation indicated by any two convergent sets selected from _P_ converges to identical results.

The Uses of Points.--The sole use of points is to facilitate the employment of the principle of Convergence to Simplicity. By this principle some simple relations in appropriate circumstances become true, when objects are considered which are sufficiently restricted in time or in space. The introduction of points enables this principle to be carried through to its ideal limit. For example, suppose _g_ (_a_, _b_, _c_) represents some statement concerning three enclosure-objects, _a_, _b_, _c_, which may be true if the objects are sufficiently restricted in extent. Let _A_, _B_, _C_ be three given points, then we define _g_ (_A_, _B_, _C_) to mean that _whatever_ three enclosure-objects _a_, _b_, _c_ are chosen, such that _a_ is a member of _A_, _b_ of _B_, and _c_ of _C_, it is _always possible_ to find three other members of _A_, _B_, _C_, namely, _x_ a member of _A_, _y_ of _B_, and _z_ of _C_, such that _aEx_, _bEy_, _cEz_, and _g_ (_x_, _y_, _z_). So by going far enough down in the tail-ends of _A_, _B_, _C_ we can always secure three objects _x_, _y_, _z_ for which _g_ (_x_, _y_, _z_) is true.

For example, let _g_ (_A_, _B_, _C_) mean "_A_, _B_, _C_ are three points in a linear row." This must be construed to mean that whatever three objects _a_, _b_, _c_ we choose, members of _A_, _B_, _C_ respectively, we can always find three objects _x_, _y_, _z_, also members of _A_, _B_, _C_ respectively, and such that _a_ encloses _x_, _b_ encloses _y_, _c_ encloses _z_, and also such that _x_, _y_, _z_ are in a linear row.

Sometimes a double convergence is necessary, namely, a convergence of conditions as well as a convergence of objects. For example, consider the statement, "the points _A_ and _B_ are two feet apart." Now, the exact statement "two feet apart" does not apply to objects. For objects _x_ and _y_ we must substitute the statement, "the distance between _x_ and _y_ lies between the limits (2 ± _e_) feet." Here _e_ is some number, less than two, which we have chosen for this statement. Then the points _A_ and _B_ are two feet apart; if, _however we choose the number e_, whatever enclosure-objects _a_ and _b_, members of _A_ and _B_ respectively, we consider, we can always find enclosure-objects _x_ and _y_, members of _A_ and _B_ respectively, such that _a_ encloses _x_ and _b_ encloses _y_, and also such that the distance between _x_ and _y_ lies between the limits (2 ± _e_) feet. It is evident, since _e_ can be chosen as small as we please, that this statement exactly expresses the condition that _A_ and _B_ are two feet apart.

Straight Lines and Planes.--But the problem of the intellectual construction of straight lines and planes is not yet sufficiently analysed. We have interpreted the meaning of the statement that three or more points are collinear, and can similarly see how to interpret the meaning of the statement that four or more points are coplanar, in either case deriving the exact geometrical

statements from vaguer statements respecting extended objects.

This procedure only contemplates groups of finite numbers of points. But straight lines and planes are conceived as containing infinite numbers of points. This completion of lines and planes is obtained by a renewed application of the principle of aggregation, just as a set of first crude thought-objects of perception are aggregated into one complete thought-object of perception. In this way repeated judgments of the collinearity of sets of points are finally, when certain conditions of interlacing are fulfilled, aggregated in the single judgment of all the points of the groups as forming one whole collinear group. Similarly for judgments of coplanarity. This process of logical aggregation can be exhibited in its exact logical analysis. But it is unnecessary here to proceed to such details. Thus we conceive our points as sorted into planes and straight lines, concerning which the various axioms of geometry hold. These axioms, in so far as they essentially require the conception of points, are capable of being exhibited as the outcome of vaguer, less exact judgments respecting the relations of extended objects.

Empty Space.--It must be observed that the points, hitherto defined, necessarily involve thought-objects of perception, and lie within the space-extension occupied by such objects. It is true that such objects are largely hypothetical, and that we can bring into our hypotheses sufficient objects to complete our lines and planes. But every such hypothesis weakens the connection between our scientific concept of nature and the actual observed facts which are involved in the actual sense-presentations.

Occam's razor, _Entia non multiplicanda præter necessitatem_, is not an arbitrary rule based on mere logical elegancy. Nor is its application purely confined to metaphysical speculation. I am ignorant of the precise reason for its metaphysical validity, but its scientific validity is obvious, namely, every use of hypothetical entities diminishes the claim of scientific reasoning to be the necessary outcome of a harmony between thought and sense-presentation. As hypothesis increases, necessity diminishes.

Commonsense thought also supports this refusal to conceive of all space as essentially depending on hypothetical objects which fill it. We think of material objects as filling space, but we ask whether any objects exist between the Earth and the Sun, between the stars, or beyond the stars. For us, space is there; the only question is whether or not it be full. But this form of question presupposes the meaning of empty space, namely, of space not containing hypothetical objects.

This brings up a wider use of the concept of points, necessitating a wider definition. Hitherto we have conceived points as indicating relations of enclosure between objects. We thus arrive at what now we will term "material points." But the idea of points can now be transformed so as to indicate the possibilities of external relations not those of enclosure. This is effected by an enlargement of the concept of ideal points, already known to geometers.

Define "material lines" to be complete collinear classes of collinear points. Consider now the set of material lines which contain a certain material point. Call such a set of lines an ideal point. This set of lines indicates a possibility of position, which is in fact occupied by that material point common to all the material lines. So this ideal point is an occupied ideal point. Now consider a set of three material lines, such that any two are coplanar, but not the whole three, and further consider the complete set of material lines such that each is coplanar with each of the three material lines first chosen. The axioms which hold for the material lines will enable us to prove that any two lines of this set are coplanar. Then the whole set of lines, including the three original lines, forms an ideal point, according to the definition in its full generality. Such an ideal point may be occupied. In that case there is a material point common to all the lines of the set, but it may be unoccupied. Then the ideal point merely indicates a possibility of spatial relations which has not been realised. It is the point of empty space. Thus the ideal points, which may or may not be occupied, are the points of geometry viewed as an applied science. These points are distributed into straight lines and planes. But any further discussion of this question will lead us into the technical subject of the axioms of geometry and their immediate consequences. Enough has been said to show how geometry arises according to the relational theory of space.

Space as thus conceived is the thought-space of the material world.

IV. Fields of Force

The thought-objects of science are conceived as directly related to this thought-space. Their spatial relations are among those indicated by the points of the thought-space. Their emergence in science has been merely a further development of processes already inherent in commonsense thought.

Relations within the complete sense-presentation were represented in thought by the concept of thought-objects of perception. All sense-presentation could not be represented in this way; also the change and disappearance of thought-objects occasioned confusion of thought. A reduction to order of this confusion was attempted by the concepts of permanent matter with primary and

secondary qualities. Finally, this has issued in the secondary qualities being traced as perception of events generated by the objects, but--as perceived--entirely disconnected with them. Also the thought-objects of perception have been replaced by molecules and electrons and ether-waves, until at length it is never the thought-object of science which is perceived, but complicated series of events in which they are implicated. If science be right, nobody ever perceived a thing, but only an event. The result is, that the older language of philosophy which still survives in many quarters is now thoroughly confusing when brought into connection with the modern concepts of science. Philosophy--that is, the older philosophy--conceives the thing as directly perceived. According to scientific thought, the ultimate thing is never perceived, perception essentially issuing from a series of events. It is impossible to reconcile the two points of view.

The advantage of the modern scientific concept is that it is enabled to "explain" the fluid vague outlines of sense-presentation. The thought-object of perception is now conceived as a fairly stable state of motion of a huge group of molecules, constantly changing, but preserving a certain identity of characteristics. Also stray sense-objects, not immediately given as part of a thought-object of perception, are now explicable: the dancing light-reflection, the vaguely heard sound, the smell. In fact, the perceived events of the scientific world have the same general definition and lack of definition, and the same general stability and lack of stability, as the sense-objects of the complete sense-presentation or as the thought-objects of perception.

The thought-objects of science, namely, molecules, atoms, and electrons, have gained in permanence. The events are reduced to changes in space-configuration. The laws determining these changes are the ultimate laws of nature.

The laws of change in the physical universe proceed on the assumption that the preceding states of the universe determine the character of the change. Thus, to know the configurations and events of the universe up to and including any instant would involve sufficient data from which to determine the succession of events throughout all time.

But in tracing the antecedents of events, commonsense thought, dealing with the world of thought-objects of perception, habitually assumes that the greater number of antecedent events can be neglected as irrelevant. Consideration of causes is restricted to a few events during a short preceding interval. Finally, in scientific thought it has been assumed that the events in an arbitrarily small preceding duration are sufficient. Thus physical quantities and their successive differential co-efficients up to any order at the instant, but with their limiting values just before that instant, are on this theory sufficient to determine the state of the universe at all times after the instant. More particular laws are assumed. But the search for them is guided by this general principle. Also it is assumed that the greater number of events in the physical universe are irrelevant to the production of any particular effect, which is assumed to issue from relatively few antecedents. These assumptions have grown out of the experience of mankind. The first lesson of life is to concentrate attention on few factors of sense-presentations, and on still fewer of the universe of thought-objects of perception.

The principle by which--consciously or unconsciously--thought has been guided is that in searching for particular causes, remoteness in time and remoteness in space are evidences of comparative disconnection of influence. The extreme form of this principle is the denial of any action at a distance either in time or space. The difficulty in accepting this principle in its crude form is, that since there are no contiguous points, only coincident bodies can act on each other. I can see no answer to this difficulty--namely, either bodies have the same location and are thus coincident, or they have different locations and are thus at a distance and do not act on each other.

This difficulty is not evaded by the hypothesis of an ether, continuously distributed. For two reasons: in the first place, the continuity of the ether does not avoid the dilemma; and secondly, the difficulty applies to time as well as to space, and the dilemma would prove that causation producing change is impossible, namely, no changed condition could be the result of antecedent circumstances.

On the other hand, a direct interaction between two bodies separated in space undoubtedly offends the conception of distance as implying physical disconnection as well as spatial relation. There is no logical difficulty in the assumption of action at a distance as in the case of its denial, but it is contradictory to persistent assumptions of that apparatus of commonsense thought which it is the main business of science to harmonise with sense-presentation, employing only the minimum of modification.

Modern science is really unconcerned with this debate. Its (unacknowledged) conceptions are really quite different, though the verbal explanations retain the form of a previous epoch. The point of the change in conception is that the old thought-object of science was conceived as possessing a simplicity not belonging to the material universe as a whole. It was secluded within a finite region of space, and changes in its circumstances could only arise from forces which formed no essential part of its nature. An

ether was called into existence to explain the active relations between these passive thought-objects. The whole conception suffers from the logical difficulties noted above. Also no clear conception can be formed of the sense in which the ether is explanatory. It is to possess a type of activity denied to the original thought-object, namely, it carries potential energy, whereas the atom possessed only kinetic energy, the so-called potential energy of an atom belonging really to the surrounding ether. The truth is, that ether is really excepted from the axiom "no action at a distance," and the axiom thereby is robbed of all its force.

The modern thought-object of science--not yet explicitly acknowledged--has the complexity of the whole material universe. In physics, as elsewhere, the hopeless endeavour to derive complexity from simplicity has been tacitly abandoned. What is aimed at is not simplicity, but persistence and regularity. In a sense regularity is a sort of simplicity. But it is the simplicity of stable mutual relations, and not the simplicity of absence of types of internal structure or of type of relation. This thought-object fills all space. It is a "field"; that is to say, it is a certain distribution of scalar and vector quantities throughout space, these quantities having each its value for each point of space at each point of time, being continuously distributed throughout space and throughout time, possibly with some exceptional discontinuities. The various types of quantity which form the field have fixed relations to each other at each point of time and space. These relations are the ultimate laws of nature.

For example, consider an electron. There is a scalar distribution of electricity, which is what is ordinarily called the electron. This scalar distribution has a volume-density ρ at the time _t_ at any point (_x_, _y_, _z_). Thus ρ is a function of (_x_, _y_, _z_, _t_), which is zero except within a restricted region. Furthermore, at any time _t_, as an essential adjunct, there is a continuous space distribution at each point of the two vectors (_X_, _Y_, _Z_), which is the electric force, and (α, β, γ), which is the magnetic force. Lastly, individuality is ascribed to the scalar electric distribution, so that in addition to its conservation of quantity--involved in the assumed laws--it is also possible to assign the velocities with which the various individual parts of the distribution are moving. Let (_u_, _v_, _w_) be this velocity at (_x_, _y_, _z_, _t_).

This whole scheme of scalar and vector quantities, namely, ρ, (_X_, _Y_, _Z_), (α, β, γ), (_u_, _v_, _w_) is interconnected by the electromagnetic laws. It follows from these laws that the electron, in the sense of the scalar distribution ρ, is to be conceived as at each instant propagating from itself an emanation which travels outwards with the velocity of light _in vacuo_, and from which (_X_, _Y_, _Z_) and (α, β, γ) can be calculated, so far as they are due to that electron. Thus the field, at any time, due to the electron as a whole depends on the previous history of the electron, the nearer to the electron the more recent being the relevant history. The whole scheme of such a field is one single thought-object of science: the electron and its emanations form one essential whole, namely one thought-object of science, essentially complex and essentially filling all space. The electron proper, namely, the scalar distribution ρ, is the focus of the whole, the essential focal property being that the field at any instant is completely determined by the previous history of the focus and of its space relations through all previous time. But the field and the focus are not independent concepts, they are essentially correlated in one organised unity, namely, they are essentially correlated terms in the field of one relation in virtue of which the entities enter into our thoughts.

The fields of a group of electrons are superposed according to the linear law for aggregation, namely, pure addition for analogous scalar quantities and the parallelogram law for analogous vectors. The changes in motion of each electron depend entirely on the resultant field in the region it occupies. Thus a field can be viewed as a possibility of action, but a possibility which represents an actuality.

It is to be noted that the two alternative views of causation are here both included. The complete field within any region of space depends on the past histories of all the electrons, histories extending backwards in proportion to their distances. Also this dependence can be conceived as a transmission. But viewing the cause which effects changes on the electron within that region, it is solely that field within the region, which field is coincident with that electron both in time and in space.

This process of conceiving the actuality underlying a possibility is the uniform process by which regularity and permanence is introduced into scientific thought, namely, we proceed from the actuality of the fact to the actuality of possibility.

In conformity with this principle, propositions are the outgrowth from actual thought-expressions, thought-objects of perceptions from crude sense-objects, hypothetical thought-objects of perception from actual thought-objects of perception, material points from hypothetical infinite suites of hypothetical thought-objects of perception, ideal points from material points, thought-objects of science from thought-objects of perception, fields of electrons from actual mutual reactions of actual electrons.

The process is a research for permanence, uniformity, and simplicity of logical relation. But it does not issue in simplicity of internal structure. Each ultimate thought-object of science retains every quality attributed to the whole scientific universe, but retains them

in a form characterised by permanence and uniformity.

V. Conclusion

We commenced by excluding judgments of worth and ontological judgments. We conclude by recalling them. Judgments of worth are no part of the texture of physical science, but they are part of the motive of its production. Mankind have raised the edifice of science, because they have judged it worth while. In other words, the motives involve innumerable judgments of value. Again, there has been conscious selection of the parts of the scientific field to be cultivated, and this conscious selection involves judgments of value. These values may be æsthetic, or moral, or utilitarian, namely, judgments as to the beauty of the structure, or as to the duty of exploring the truth, or as to utility in the satisfaction of physical wants. But whatever the motive, without judgments of value there would have been no science.

Again, ontological judgments were not excluded by reason of any lack of interest. They are in fact presupposed in every act of life: in our affections, in our self-restraints, and in our constructive efforts. They are presupposed in moral judgments. The difficulty about them is the absence of agreement as to the method of harmonising the crude judgments of commonsense.

Science does not diminish the need of a metaphysic. Where this need is most insistent is in connection with what above has been termed "the actuality underlying a possibility." A few words of explanation may render the argument clearer, although they involve a rash approach to metaphysical heights which it is not the purpose of this paper to explore.

The conception of subject and object in careless discussion covers two distinct relations. There is the relation of the whole perceiving consciousness to part of its own content, for example, the relation of a perceiving consciousness to an object of redness apparent to it. There is also the relation of a perceiving consciousness to an entity which does not exist in virtue of being part of the content of that consciousness. Such a relation, so far as known to the perceiving consciousness, must be an inferred relation, the inference being derived from an analysis of the content of the perceiving consciousness.

The bases for such inferences must be elements in consciousness directly known as transcending their immediate presentation in consciousness. Such elements are universal logical truths, moral and æsthetic truths, and truths embodied in hypothetical propositions. These are the immediate objects of perception which are other than the mere affections of the perceiving subject. They have the property of being parts of the immediate presentations for individual subjects and yet more than such parts. All other existence is inferred existence.

In this chapter we are more directly concerned with truths embodied in hypothetical propositions. Such truths must not be confused with any doubtfulness which attaches to our judgments of the future course of natural phenomena. A hypothetical proposition, like a categorical judgment, may or may not be doubtful. Also like a categorial judgment, it expresses a fact. This fact is twofold: as a presentation in consciousness, it is just this hypothetical judgment; as expressing a categorical fact, it states a relation which lies beyond consciousness, holding between entities thereby inferred.

But this metaphysical analysis, short though it be, is probably wrong, and at the best will only command very partial assent. Certainly; and this admission brings out the very point which I wished to make. Physical science is based on elements of thought, such as judgments registering actual perceptions, and judgments registering hypothetical perceptions which under certain circumstances would be realised. These elements form the agreed content of the apparatus of commonsense thought. They require metaphysical analysis; but they are among the data from which metaphysics starts. A metaphysic which rejects them has failed, in the same way as physical science has failed when it is unable to harmonise them into its theory.

Science only renders the metaphysical need more urgent. In itself it contributes little directly to the solution of the metaphysical problem. But it does contribute something, namely, the exposition of the fact that our experience of sensible apparent things is capable of being analysed into a scientific theory, a theory not indeed complete, but giving every promise of indefinite expansion. This achievement emphasises the intimate relation between our logical thought and the facts of sensible apprehension. Also the special form of scientific theory is bound to have some influence. In the past false science has been the parent of bad metaphysics. After all, science embodies a rigorous scrutiny of one part of the whole evidence from which metaphysicians deduce their conclusions.

CHAPTER VIII

SPACE, TIME, AND RELATIVITY

(_Paper read to Section A at the Manchester Meeting of the British Association, 1915, and later before the Aristotelian Society_)

FUNDAMENTAL Problems concerning space and time have been considered from the standpoints created by many different sciences. The object of this paper is the humble one of bringing some of these standpoints into relation with each other. This necessitates a very cursory treatment of each point of view.

Mathematical physicists have evolved their theory of relativity to explain the negative results of the Morley-Michelson experiment and of the Trouton experiment. Experimental psychologists have considered the evolution of spatial ideas from the crude sense-data of experience. Metaphysicians have considered the majestic uniformity of space and time, without beginning and without end, without boundaries, and without exception in the truths concerning them; all these qualities the more arresting to our attention from the confused accidental nature of the empirical universe which is conditioned by them. Mathematicians have studied the axioms of geometry, and can now deduce all that is believed to be universally true of space and of time by the strictest logic from a limited number of assumptions.

These various lines of thought have been evolved with surprisingly little interconnection. Perhaps it is as well. The results of science are never quite true. By a healthy independence of thought perhaps we sometimes avoid adding other people's errors to our own. But there can be no doubt that the normal method of cross-fertilising thought is by considering the same, or allied problems to our own, in the form which they assume in other sciences.

Here I do not propose to enter into a systematic study of these various chapters of science. I have neither the knowledge nor the time.

First, let us take the ultimate basis of any theory of relativity. All space measurement is from stuff in space to stuff in space. The geometrical entities of empty space never appear. The only geometrical properties of which we have any direct knowledge are properties of those shifting, changeable appearances which we call things in space. It is the sun which is distant, and the ball which is round, and the lamp-posts which are in linear order. Wherever mankind may have got its idea of an infinite unchangeable space from, it is safe to say that it is not an immediate deliverance of direct observation.

There are two antagonistic philosophical ways of recognising this conclusion.

One is to affirm that space and time are conditions for sensible experience, that without projection into space and time sensible experience would not exist. Thus, although it may be true to say that our knowledge of space and time is given in experience, it is not true to say that it is deduced from experience in the same sense that the Law of Gravitation is so deduced. It is not deduced, because in the act of experiencing we are necessarily made aware of space as an infinite given whole, and of time as an unending uniform succession. This philosophical position is expressed by saying that space and time are _a priori_ forms of sensibility.

The opposed philosophical method of dealing with the question is to affirm that our concepts of time and space are deductions from experience, in exactly the same way as the Law of Gravitation is such a deduction. If we form exact concepts of points, lines and surfaces, and of successive instants of time, and assume them to be related as expressed by the axioms of geometry and the axioms for time, then we find that we have framed a concept which, with all the exactness of which our observations are capable, expresses the facts of experience.

These two philosophic positions are each designed to explain a certain difficulty. The _a priori_ theory explains the absolute universality ascribed to the laws of space and time, a universality not ascribed to any deduction from experience. The experiential theory explains the derivation of the space-time concepts without introducing any other factors beyond those which are admittedly present in framing the other concepts of physical science.

But we have not yet done with the distinctions which in any discussion of space or time must essentially be kept in mind. Put aside the above question as to how these space-time concepts are related to experience--What are they when they are formed?

We may conceive of the points of space as self-subsistent entities which have the indefinable relation of being occupied by the ultimate stuff (matter, I will call it) which is there. Thus, to say that the sun is _there_ (wherever it is) is to affirm the relation of occupation between the set of positive and negative electrons which we call the sun and a certain set of points, the points having an existence essentially independent of the sun. This is the absolute theory of space. The absolute theory is not popular just now, but it has very respectable authority on its side--Newton, for one--so treat it tenderly.

The other theory is associated with Leibniz. Our space concepts are concepts of relations between things in space. Thus there is no such entity as a self-subsistent point. A point is merely the name for some peculiarity of the relations between the matter which is, in common language, said to be in space.

It follows from the relative theory that a point should be definable in terms of the relations between material things. So far as I am aware, this outcome of the theory has escaped the notice of mathematicians, who have invariably assumed the point as the ultimate starting ground of their reasoning. Many years ago I explained some types of ways in which we might achieve such a definition, and more recently have added some others. Similar explanations apply to time. Before the theories of space and time have been carried to a satisfactory conclusion on the relational basis, a long and careful scrutiny of the definitions of points of space and instants of time will have to be undertaken, and many ways of effecting these definitions will have to be tried and compared. This is an unwritten chapter of mathematics, in much the same state as was the theory of parallels in the eighteenth century.

In this connection I should like to draw attention to the analogy between time and space. In analysing our experience we distinguish events, and we also distinguish things whose changing relations form the events. If I had time it would be interesting to consider more closely these concepts of events and of things. It must suffice now to point out that things have certain relations to each other which we consider as relations between the space extensions of the things; for example, one space can contain the other, or exclude it, or overlap it. A point in space is nothing else than a certain set of relations between spatial extensions.

Analogously, there are certain relations between events which we express by saying that they are relations between the temporal durations of these events, that is, between the temporal extensions of the events. [The durations of two events A and B may one precede the other, or may partially overlap, or may one contain the other, giving in all six possibilities.] The properties of the extension of an event in time are largely analogous to the extension of an object in space. Spatial extensions are expressed by relations between objects, temporal extensions by relations between events.

The point in time is a set of relations between temporal extensions. It needs very little reflection to convince us that a point in time is no direct deliverance of experience. We live in durations, and not in points. But what community, beyond the mere name, is there between extension in time and extension in space? In view of the intimate connection between time and space revealed by the modern theory of relativity, this question has taken on a new importance.

I have not thought out an answer to this question. I suggest, however, that time and space embody those relations between objects on which depends our judgment of their externality to ourselves. Namely, location in space and location in time both embody and perhaps necessitate a judgment of externality. This suggestion is very vague, and I must leave it in this crude form.

Diverse Euclidean Measure Systems

Turning now to the mathematical investigations on the axioms of geometry, the outcome, which is most important for us to remember, is the great separation which it discloses between non-metrical projective geometry, and metrical geometry. Non-metrical projective geometry is by far the more fundamental. Starting with the concepts of points, straight lines, and planes (of which not all three need be taken as indefinable), and with certain very simple non-metrical properties of these entities--such as, for instance, that two points uniquely determine a straight line--nearly the whole of geometry can be constructed. Even quantitative coordinates can be introduced, to facilitate the reasoning. But no mention of distance, area, or volume, need have been introduced. Points will have an order on the line, but order does not imply any settled distance.

When we now inquire what measurements of distance are possible, we find that there are different systems of measurement all equally possible. There are three main types of system: any system of one type gives Euclidean geometry, any system of another type gives Hyperbolic (or Lobatchewskian) geometry, any system of the third type gives Elliptic geometry. Also different beings, or the same being if he chooses, may reckon in different systems of the same type, or in systems of different types. Consider the example which will interest us later. Two beings, A and B, agree to use the same three intersecting lines as axes of _x_, _y_, _z_.

They both employ a system of measurement of the Euclidean type, and (what is not necessarily the case) agree as to the plane at infinity. That is, they agree as to the lines which are parallel. Then with the usual method of rectangular Cartesian axes, they agree that the coordinates of P are the lengths ON, NM, MP. So far all is harmony. A fixes on the segment OU_{1}, on O_x_, as being the unit length, and B on the segment OV_{1}, on O_x_. A calls his coordinates (_x_, _y_, _z_), and B calls them (X, Y, Z).

Then it is found [since both systems are Euclidean] that, whatever point P be taken,

$X = \beta_x_$, $Y = \gamma_y_$, $Z = \delta_z_$. [$\beta \neq \gamma \neq \delta$.]

They proceed to adjust their differences, and first take the _x_-coordinates. Obviously they have taken different units of length along O_x_. The length OU_{1}, which A calls one unit, B calls β units. B changes his unit length to OU_{1}, from its original length OV_{1}, and obtains X = _x_. But now, as he must use the same unit for all his measurements, his other coordinates are altered in the same ratio. Thus we now have

$X = _x_$, $Y = \gamma_y_/\beta$, $Z = \delta_z_/\beta$.

The fundamental divergence is now evident. A and B agree as to their units along O_x_. They settled that by taking along that axis a given segment OU_{1} as having the unit length. But they cannot agree as to what segment along O_y_ is equal to OU_{1}. A says it is OU_{2}, and B that it is OU_{2}′. Similarly for lengths along OZ.

The result is that A's spheres

$_x_^2 + _y_^2 + _z_^2 = _r_^2$,

are B's ellipsoids,

$X^2 + \beta^2Y^2/\gamma^2 + \beta^2Z^2/\delta^2 = _r_^2$, _i. e._ $X^2/\beta^2 + Y^2/\gamma^2 + Z^2/\delta^2 = _r_^2/\beta^2$.

Thus the measurement of angles by the two is hopelessly at variance.

If $\beta \neq \gamma \neq \delta$, there is one, and only one, set of common rectangular axes at O, namely that from which they started. If $\gamma = \delta$, but $\beta \neq \gamma$, then there are a singly infinite number of common rectangular axes found by rotating the axes round O_x_. This is, for us, the interesting case. The same phenomena are reproduced by transferring to any parallel axes.

The root of the difficulty is, that A's measuring rod, which for him is a rigid invariable body, appears to B as changing in length when turned in different directions. Similarly all measuring rods, satisfactory to A, violate B's immediate judgment of invariability, and change according to the same law. There is no way out of the difficulty. Two rods ρ and σ coincide whenever laid one on the other; ρ is held still, and both men agree that it does not change. But σ is turned round. A says it is invariable, B says it changes. To test the matter, ρ is turned round to measure it, and exactly fits it. But while A is satisfied, B declares that ρ has changed in exactly the same way as did σ. Meanwhile B has procured two material rods satisfactory to him as invariable, and A makes exactly the same objections.

We shall say that A and B employ diverse Euclidean metrical systems.

The most extraordinary fact of human life is that all beings seem to form their judgments of spatial quantity according to the same metrical system.

Relativity in Modern Physics

Owing to the fact that points of space are incapable of direct recognition, there is a difficulty--apart from any abstract question of the nature of space--in deciding on the motion to be ascribed to any body. Even if there be such a thing as absolute position, it is impossible in practice to decide directly whether a body's absolute position has changed. All spatial measurement is relative to matter.

Newton's laws of motion in their modern dress evade this difficulty by asserting that a framework of axes of coordinates can be defined by their relations to matter such that, assuming these axes to be at rest, and all velocities to be measured relatively to them, the laws hold. The same expedient has to be employed for time, namely, the laws hold when the measurement of the flow of time is made by the proper reference to periodic events. Thus the laws assert that the framework and the natural clock adapted for their use have been successfully found.

But, if one framework will do, an infinity of others serve equally well; namely, not only--as is of course the case--all those at rest relatively to the first framework, but also all those which move without relative rotation with uniform velocity relatively to the first. This whole set of frameworks is on a level in respect to Newton's laws. We will call them Dynamical frameworks.

Now, suppose there are two observers, A and B. They agree in their non-metrical projective geometry, _e.g._, what A calls a straight line so does B. They also both apply a Euclidean metrical system of measurement to this space. Their two metrical systems also agree in having the same plane at infinity, that is, lines which are parallel for A are also parallel for B. Furthermore, they have both successfully applied Newton's laws to the movement of matter, and agree in having the same sets of dynamical axes. But the framework (among these sets) which A chooses to regard as at rest is different from the frame (among the same sets) which B so regards.

Without alteration of their respective judgment of rest, they choose their co-ordinate axes so that the origins (O for A, and O′ for B) are in relative motion along OO′, which is the axis of _x_ for both.

Further, since OO′ is the line of symmetry of their diverse Euclidean systems, we assume that the two measure-systems agree for planes perpendicular to OO′, _i.e._, we assume a symmetry round OO′. Then if, for A at O, the distance OO′ be ξ, the relations at any instant between A's coordinates (_x_, _y_, _z_) and B's coordinates (_x′_, _y′_, _z′_) for the same point P are given by

_x′_ = β(_x_ - ξ), _y′_ = _y_, _z′_ = _z_.

Also, according to A's clock, O′ is moving forward with a uniform velocity _v_, and we measure A's time from the instant of the coincidence of O and O′.

Thus

ξ = _vt_,

and

_x′_ = β(_x_ - _vt_), _y′_ = _y_, _z′_ = _z_.

We now consider B's clock, and ask for the most general supposition which is consistent with the fact that their judgments as to the fact of uniform motion are in agreement.

We do not assume that events in various parts of space which A considers to be simultaneous are so considered by B. But we assume that at any point P, with coordinates (_x_, _y_, _z_) for A, there is a determinate relation between B's time T and _x_, _y_, _z_, _t_.

Put

T = *f* (_x_, _y_, _z_, _t_).

Write

P = δT/δ_x_, Q = δT/δ_y_, R = δT/δ_z_, S = δT/δ_t_.

Now suppose that the point P is moving, and that (_u_{1}, _u_{2}, _u_{3}) is its set of component velocities along the axes according to A's "space and clock" system, and (U_{1}, U_{2}, U_{3}) is its set of component velocities according to B's "space and clock" system. Then by mere differentiation it follows after a short mathematical deduction that

U_{1} = {(_d_β/_dt_)(_x_ - _vt_) + β(_u_{1} - _v_)}/{P_u_{1} + Q_u_{2} + R_u_{3} + S}, U_{2} = _u_{2}/{P_u_{1} + Q_u_{2} + R_u_{3} + S}, U_{3} = _u_{3}/{P_u_{1} + Q_u_{2} + R_u_{3} + S}.

But we have assumed that, whatever the direction of the resultant velocity (_u_{1}, _u_{2}, _u_{3}), the velocities (U_{1}, U_{2}, U_{3}) and (_u_{1}, _u_{2}, _u_{3}) are both uniform when either is uniform.

Hence it is easily proved that β, P, Q, R, S are independent of the coordinates (_x_, _y_, _z_) and of the time _t_. In other words, they are constant.

Hence we obtain

U_{1} = β(_u_{1} - _v_)/{P_u_{1} + Q_u_{2} + R_u_{3} + S},

and

T = P_x_ + Q_y_ + R_z_ + S_t_.

But we assumed that OO′, _i.e._, O_x_, is an axis of symmetry. It follows from this assumption that

Q = R = 0.

We thus obtain the simplified results

T = P_x_ + S_t_, } U_{1} = β(_u_{1} - _v_)/(P_u_{1} + S), } (I) U_{2} = _u_{2}/(P_u_{1} + S), } U_{3} = _u_{3}/(P_u_{1} + S). }

Here we remember that (_u_{1}, _u_{2}, _u_{3}) are the velocities of any particle according to A's "space and clock" system, and that (U_{1}, U_{2}, U_{3}) are the velocities of the same point according to B's "space and clock" system. We have obtained the most general relations consistent with the facts that (1) they both employ Euclidean systems, related as described above, and (2) they agree in their judgments on the uniformity of velocity.

We now compare their judgments on the magnitudes of velocities.

Let the magnitude of the velocity of P be V according to A's judgment, and V′ according to B's' judgment.

Then

V^2 = _u_{1}^2 + _u_{2}^2 + _u_{3}^2, V′^2 = U_{1}^2 + U_{2}^2 + U_{3}^2.

Also we can put

_u_{1} = _l_V, _u_{2} = _m_V, _u_{3} = _n_V,

where (_l_, _m_, _n_) have nothing to do with the magnitude V, but simply depend on the direction of motion. In fact (_l_, _m_, _n_) are the "direction cosines" of the velocity according to A's judgment. By substituting in the above equation for V^2 we see that

_l_^2 + _m_^2 + _n_^2 = 1.

Now, substituting for (_u_{1}, _u_{2}, _u_{3}) in the equations (I) above, and squaring and adding, and eliminating _m_^2 + _n_^2 by the relation just found, we at once find

V′^2 = ((β^2 - 1)V^2_l_^2 - 2β^2V_vl_ + β^2_v_^2 + V^2)/(PV_l_ + S)^2.

It is thus seen that in general the relation of V′ to V depends on the direction cosine _l_. Now _l_ is the cosine of the angle which the direction of the velocity V makes with O_x_, according to A's judgment.

The meaning of this relation is, that if A discharges, from guns at the point P, shells with a given muzzle velocity V according to his judgment, B will consider that their muzzle velocities are different from each other, except in the case of pairs of guns equally inclined to the axis OO′. Instances of this type of diversity of judgment can be noted any day by any one who looks out of the window of a railway carriage, and forgets that he is travelling.

Now, suppose the velocity V′ bears a relation to the velocity V, which is independent of _l_. Then _l_ must disappear from the above formula. There are two conditions to be satisfied

One condition is

V^2 = β^2_v_^2/(β^2 - 1),

or in a more convenient form

β^2 = 1/(1 - _v_^2/V^2).

The meaning of this condition is, that there is one, and only one, muzzle velocity V (according to A's judgment), namely, the muzzle velocity given by the above formula, which can have the property that B will judge that all the guns are firing in their diverse directions with one common muzzle velocity.

Let us now suppose that V has this peculiar value: that is, if we look on this value V as known, we must suppose that β is given by the second of the above formulæ.

The other condition allows P and S to be put in the forms

P = -β_v_/λV^2, S = β/λ,

where

V′ = λV.

Thus we have the bundle of formulæ

β^2 = 1/(1 - _v_^2/V^2), T = β{_t_ - _vx_/V^2}/λ, V′ = λV.

The value which we give to λ is purely a matter for the adjustment of units. If we want A and B to agree in their judgments of the magnitude of this peculiar muzzle-velocity, we put λ = 1.

We then get the formulæ usually adopted, namely

β^2 = 1/(1 - _v_^2/V^2), } T = β{_t_ - _vx_/V^2}, } (II) V′ = V. }

But if we prefer that A and B should reckon (according to A's judgment) in the same units of time, we put λ = β, and obtain

β^2 = 1/(1 - _v_^2/V^2), T = (_t_ - _vx_)/V^2, V′ = βV.

But A and B are in any case in such hopeless difficulties over their comparisons of time-judgments that the detail of using the same units does not help them much. Accordingly the formulæ marked (II) are those used. Thus A and B agree in their judgments as to the magnitude of one special velocity V, whatever may be the direction in which the entity possessing it is moving.

In order to reach this measure of agreement, they have to disagree as to their space judgments and their time judgments. The root cause of their disagreement is their diverse judgment as to which axis system is to be taken at rest for the purpose of measuring velocities.

Before discussing the nature of the disagreement disclosed in formula (II), let us ask why we should bring these difficulties on our heads by supposing that two people in relative motion, who both (for the purpose of measuring velocities) assume that they are at rest, should agree in their judgments in respect to this special velocity V.

Such an agreement has no counterpart in any of our obvious judgments made from railway carriages. Surely we can wait till the contingency occurs before discussing the confusion which it creates.

But the contingency has occurred. It occurs when we consider the velocity of light. Perhaps I may venture to remind a philosophical society that light moves so very quickly that it is difficult to consider its velocity at all. So we need not be surprised that this peculiar fact concerning its velocity is not more obvious.

Now V being the velocity of light, unless _v_ is large, _v_/V (and still more _v_^2/V^2) will be quite inappreciable. The only velocity ready to hand which is big enough to give _v_/V an appreciable value is the velocity of the earth in its orbit.

Many diverse experiments have been made, and they all agree in concluding that a man who assumes the earth to be at rest will find by measurement that the velocity of light is the same in all directions. Furthermore, when the same man turns his attention to interstellar or interplanetary phenomena, and assumes the sun to be at rest, he will again find the velocity of light to be the same in all directions. These are well-attested experiments made at long intervals of time.

This is the exact contingency contemplated above.

Again the velocity of light _in vacuo_ has recently taken on a new dignity. It used to be one among other wave velocities such as the velocity of sound in air, or in water, or the velocity of surface waves in water. But Clerk Maxwell discovered that all electromagnetic influences are propagated with the velocity of light, and now modern physical science half suspects that electromagnetic influences are the only physical influences which relate the changes in the physical world. Accordingly the velocity of light becomes the fundamental natural velocity, and experiment shows that our judgment of its magnitude is not affected by our

choice of the framework at rest, so long as we keep to a set of dynamical axes. These experiments on light have been confirmed by other electromagnetic experiments not involving light.

Thus we are driven to equations (II), where V is the velocity of light.

The first conclusion to be drawn from equations (II) is that two people who make different choices of bodies at rest will disagree as to their measuring rods in the way described above. There is no peculiar difficulty about that. The only wonder is that all people agree so well in their judgments as to metrical systems. A mathematical angel would naturally expect incarnate men to be in violent disagreement on this subject.

But the case of time is different. For simplicity of statement we speak of A as at O, and B as at O′. We remember that O′ is moving relatively to O with velocity _v_ in direction OO′. Suppose A and B are looking in this direction; and they both measure their time from the instant when they met, as O′ passed over O. Then we have

T = ((_t_ - _vx_)/V^2)/((1 - _v_^2)/V^2).

Now, suppose we consider all the events all over space which A considers to have happened simultaneously at the time _t_. The events of this set which occurred anywhere on a plane perpendicular to OO′ at a distance _x_ in front of O (according to A's reckoning), will have occurred according to B's reckoning at the time T as given above. Let us fix our attention on the fact that B does not consider all these events to be simultaneous. For let T_{1}, and T_{2} be B's times for such events on planes _x__{1}, and _x__{2}. Then

T_{1} - T_{2} = _v_(_x__{2} - _x__{1})/(V^2 - _v_^2).

Thus if _x__{2} be greater than _x__{1}, T_{2} is less than T_{1}. Thus B judges the more distant events in front of him to have happened earlier than the nearer events in front of him, and _vice versa_ for the events behind. This disturbance of the judgment of simultaneity is the fundamental fact. Obviously the measurement of time intervals is a detail compared to simultaneity. A may think a sermon long, and B may think it short, but at least they should both agree that it stopped when the clock hand pointed at the hour. The worst of the matter is that so far as any test can be applied there is no method of discriminating between the validities of their judgments.

Thus we are confronted with two distinct concepts of the common world, A's space-time concept, and B's space-time concept. Who is right? It is no use staying for an answer. We must follow the example of the wise old Roman, and pass on to other things.

Thus estimates of quantity in space and time, and, to some extent, even estimates of order, depend on the individual observer. But what are the crude deliverances of sensible experience, apart from that world of imaginative reconstruction which for each of us has the best claim to be called our real world? Here the experimental psychologist steps in. We cannot get away from him. I wish we could, for he is frightfully difficult to understand. Also, sometimes his knowledge of the principles of mathematics is rather weak, and I sometimes suspect---- No, I will not say what I sometimes think: probably he, with equal reason, is thinking the same sort of thing of us.

I will, however, venture to summarise conclusions, which are, I believe, in harmony with the experimental evidence, both physical and psychological, and which are certainly suggested by the materials for that unwritten chapter in mathematical logic which I have already commended to your notice. The concepts of space and time and of quantity are capable of analysis into bundles of simpler concepts. In any given sensible experience it is not necessary, or even usual, that the whole complete bundle of such concepts apply. For example, the concept of externality may apply without that of linear order, and the concept of linear order may apply without that of linear distance.

Again, the abstract mathematical concept of a space-relation may confuse together distinct concepts which apply to the given perceptions. For example, linear order in the sense of a linear projection from the observer is distinct from linear order in the sense of a row of objects stretching across the line of sight.

Mathematical physics assumes a given world of definitely related objects, and the various space-time systems are alternative ways of expressing those relations as concepts in a form which also applies to the immediate experience of observers.

Yet there must be one way of expressing the relations between objects in a common external world. Alternative methods can only arise as the result of alternative standpoints; that is to say, as the result of leaving something added by the observer sticking (as it

were) in the universe.

But this way of conceiving the world of physical science, as composed of hypothetical objects, leaves it as a mere fairy tale. What is really actual are the immediate experiences. The task of deductive science is to consider the concepts which apply to these data of experience, and then to consider the concepts relating to these concepts, and so on to any necessary degree of refinement. As our concepts become more abstract, their logical relations become more general, and less liable to exception. By this logical construction we finally arrive at conceptions, (i) which have determinate exemplifications in the experience of the individuals, and (ii) whose logical relations have a peculiar smoothness. For example, conceptions of mathematical time, of mathematical space, are such smooth conceptions. No one lives in "an infinite given whole," but in a set of fragmentary experiences. The problem is to exhibit the concepts of mathematical space and time as the necessary outcome of these fragments by a process of logical building up. Similarly for the other physical concepts. This process builds a common world of conceptions out of fragmentary worlds of experience. The material pyramids of Egypt are a conception, what is actual are the fragmentary experiences of the races who have gazed on them.

So far as science seeks to rid itself of hypothesis, it cannot go beyond these general logical constructions. For science, as thus conceived, the divergent time orders considered above present no difficulty. The different time systems simply register the different relations of the mathematical construct to those individual experiences (actual or hypothetical) which could exist as the crude material from which the construct is elaborated.

But after all it should be possible so to elaborate the mathematical construct so as to eliminate specific reference to particular experiences. Whatever be the data of experience, there must be something which can be said of them as a whole, and that something is a statement of the general properties of the common world. It is hard to believe that with proper generalisation time and space will not be found among such properties.

Commentary added on reading the Paper before the Aristotelian Society

The first six pages of the paper consist of a summary of ideas which ought to be in our minds while considering problems of time and space. The ideas are mostly philosophical, and the summary has been made by an amateur in that science; so there is no reason to ascribe to it any importance except that of a modest reminder. There are only two points in this summary to which I would draw attention.

On pp. 192 and 193 there occurs--

"Wherever mankind ... unending uniform succession."

If I understand Kant rightly--which I admit to be very problematical--he holds that in the act of experience we are aware of space and time as ingredients necessary for the occurrence of experience. I would suggest--rather timidly--that this doctrine should be given a different twist, which in fact turns it in the opposite direction--namely, that in the act of experience we perceive a whole formed of related differentiated parts. The relations between these parts possess certain characteristics, and time and space are the expressions of some of the characteristics of these relations. Then the generality and uniformity which are ascribed to time and space express what may be termed the uniformity of the texture of experience.

The success of mankind--modest though it is--in deducing uniform laws of nature is, so far as it goes, a testimony that this uniformity of texture goes beyond those characteristics of the data of experience which are expressed as time and space. Time and space are necessary to experience in the sense that they are characteristics of our experience; and, of course, no one can have our experience without running into them. I cannot see that Kant's deduction amounts to much more than saying that "what is, is"--true enough, but not very helpful.

But I admit that what I have termed the "uniformity of the texture of experience" is a most curious and arresting fact. I am quite ready to believe that it is a mere illusion; and later on in the paper I suggest that this uniformity does not belong to the immediate relations of the crude data of experience, but is the result of substituting for them more refined logical entities, such as relations between relations, or classes of relations, or classes of classes of relations. By this means it can be demonstrated--I think--that the uniformity which must be ascribed to experience is of a much more abstract attenuated character than is usually allowed. This process of lifting the uniform time and space of the physical world into the status of logical abstractions has also the advantage of recognising another fact, namely, the extremely fragmentary nature of all direct individual experience.

My point in this respect is that fragmentary individual experiences are all that we know, and that all speculation must start from these _disjecta membra_ as its sole datum. It is not true that we are directly aware of a smooth running world, which in our speculations we are to conceive as given. In my view the creation of the world is the first unconscious act of speculative thought; and the first task of a self-conscious philosophy is to explain how it has been done.

There are roughly two rival explanations. One is to assert the world as a postulate. The other way is to obtain it as a deduction, not a deduction through a chain of reasoning, but a deduction through a chain of definitions which, in fact, lifts thought on to a more abstract level in which the logical ideas are more complex, and their relations are more universal. In this way the broken limited experiences sustain that connected infinite world in which in our thoughts we live. There are three more remarks while on this point I wish to make--

(i) The fact that immediate experience is capable of this deductive superstructive must mean that it itself has a certain uniformity of texture. So this great fact still remains.

(ii) I do not wish to deny the world as a postulate. Speaking without prejudice, I do not see how in our present elementary state of philosophical advance we can get on without middle axioms, which, in fact, we habitually assume.

My position is, that by careful scrutiny we should extrude such postulates from every part of our organised knowledge in which it is possible to do without them.

Now, physical science organises our knowledge of the relations between the deliverances of our various senses. I hold that in this department of knowledge such postulates, though not entirely to be extruded, can be reduced to a minimum in the way which I have described.

I have not the slightest knowledge of theories respecting our emotions, affections, and moral sentiments, and I can well believe that in dealing with them further postulates are required. And in practice I recognise that we all make such postulates, uncritically.

(iii) The next paragraphs on pp. 193 and 194 are as follows--

"The opposed philosophical method ... physical science."

It will be noted that, in the light of what has just been stated, the first of these paragraphs (which, I hope, faithfully expresses the experimental way of approaching the problem) really obscures the point which I have been endeavouring to make. The phrase, "If we form the exact concepts of points, etc.," is fatally ambiguous as between the method of postulating entities with assigned relations, and the method of forming logical constructions, and thus reaching points, etc., as the result of a chain of definitions.

Turning now to pp. 194-195, we come to the following paragraphs--

"The other theory ... eighteenth century."

We note again that the relational theory of space from another point of view brings us back to the idea of the fundamental space-entities as being logical constructs from the relations between things. The difference is, that this paragraph is written from a more developed point of view, as it implicitly assumes the things in space, and conceives space as an expression of certain of their relations. Combining this paragraph with what has gone before, we see that the suggested procedure is first to define "things" in terms of the data of experience, and then to define space in terms of the relations between things.

This procedure is explicitly assumed in the next short paragraph: "In this connection ... from the events."

The gist of the remaining paragraphs of this section is contained in the paragraph at the bottom of p. 196: "The point in time ... new importance."

The sentence, "We live in durations, and not in points," can be amplified by the addition, "We live in space-extensions and not in space-points."

It must be noted that "whole and part" as applied to extensions in space or time must be different from the "all and some" of logic, unless we admit points to be the fundamental entities. For "spatial whole and spatial part" can only mean "all and some" if they really mean "all the points and some of the points." But if extensions and their relations are more fundamental than points, this interpretation is precluded. I suggest that "spatial whole and spatial part" is intimately connected with the fundamental relation between things from which our space ideas spring.

The relation of space whole to space part has many formal properties which are identical with the properties of "all and some." Also when points have been defined, we can replace it by the conception of "all the points and some of the points." But the confusion between the two relations is fatal to sound views on the subject.

Diverse Euclidean Measure Systems

The next section deals with the measure systems applicable to space.

A measure system is a group of congruent transformations of space into itself. Consider a rigid body occupying all space. Let this body be moved in any way so that the particles of the body which occupied points P_{1}, P_{2}, P_{3}, etc., now occupy points Q_{1}, Q_{2}, Q_{3}, etc. Then any point P_{1} in space is uniquely related to the corresponding point Q_{1} in space by a one-to-one transformation with certain characteristics. By the aid of these transformations we can achieve the definition of distance in a way which definitely determines the distance between any two points, provided that we can define what we mean by a congruent transformation without introducing the idea of distance. If we introduced the idea of distance, we should simply say that a congruent transformation is one which leaves all distances unchanged, _i. e._, if P_{1}, P_{2} are transformed into Q_{1}, Q_{2} then the distance P_{1}P_{2} is equal to the distance Q_{1}Q_{2}.

But mathematicians have succeeded in defining congruent transformations without any reference to distance.

There are alternative groups of such congruent transformations, and each group gives a different measure system for space. The distance P_{1}P_{2} may equal the distance Q_{1}Q_{2} for one measure system, and will not equal it for another measure system. All these different measure systems are on the same level, equally applicable. A being with a strong enough head could think of them all at once as applying to space. The result so far as it interests us in respect to the theory of relativity is explained on pp. 197-200, ending with "The most extraordinary fact ... same metrical system." This final sentence bears on Poincaré's assertion that the measure system adopted is purely "conventional." I presume that by "conventional" a certain arbitrariness of choice is meant; and in that case, I must express entire dissent. It is true that within the circle of geometrical ideas there is no means of giving any preference to any one measure system, and any one is as good as any other. But it is not true that if we look at a normal carriage wheel, and at an oval curve one foot broad and ten feet long, we experience any arbitrariness of judgment in deciding which has approximately the form of a circle. Accordingly to Poincaré the choice between them, as representing a circle, is entirely conventional.

Again, we equally form immediate judgments as to whether a body is approximately rigid. We know that a paving stone is rigid, and that a concertina is not rigid. This again necessitates a determinate measure system, selected from among the others.

Accordingly we conclude that (i) each being does, in fact, employ a determinate measure system, which remains the same, except possibly for very small variations, and (ii) the measure systems of different human beings agree, to within the limits of our observations. These conclusions are not the less extraordinary because no plain man has ever doubted them.

It is an interesting subject to investigate exactly what are the fundamental uniformities of experience which necessitate this conclusion. It is not so easy as it looks, since we have to divest ourselves of all aid of scientific hypothesis if our conclusions are to be demonstrative.

Relativity in Modern Physics

Pp. 201-202, "Owing to the fact ... which B so regards."

The fundamental formulæ for the theory of relativity are the relations between diverse co-ordinate systems given on p. 203, and formulæ II at the bottom of p. 207. The general explanation of one method in which these formulæ arise--namely, Einstein's method--is given on pp. 201-211. Namely, we seek the condition that for all dynamical axes the velocity of light should be the same, and the same in all directions. It should be noted that the experiments which, so far as they go, confirm these formulæ, can also be explained in another way which makes the theory of relativity unnecessary. We need only ascribe to the ether a certain property of contraction in the direction of motion, and the thing is done. So no one need be bludgeoned into accepting the rather bizarre doctrine of relativity, nor indeed any other scientific generalisation. The good old homely ether, which we all know, can in this case serve the purpose. Just as an author of genius, if he lives long enough, survives the inevitable accusation of immorality, so the ether by dint of persistence has outlived all reputation of extravagance. But if we detach ourselves from the glib phraseology concerning it, the scientific ether is uncommonly like the primitive explanation of the soul, as a little man inside us, which can

sometimes be caught escaping in the form of a butterfly. As soon as the ether has to be patched up with special properties to explain special experiments, its scientific use is problematical, and its philosophic use is _nil_.

Philosophically the ether seems to me to be an ambitious attempt to give a complete explanation of the physical universe by making an elephant stand on a tortoise. Scientifically it has a perfectly adequate use by veiling the extremely abstract character of scientific generalisations under a myth, which enables our imaginations to work more freely. I am not advocating the extrusion of ether from our scientific phraseology, even though at special points we have to abandon it.

But the key to the reasons why it is worth while to consider seriously the doctrine of relativity is to be found on pp. 209, 210: "Again the velocity of light ... not involving light." Namely, we have begun to suspect that all physical influences require time for their propagation in space. This generalisation is a long way from being proved. Gravitation stands like a lion in the path. But if it be the case, then all idea of an immediate presentation to us of an aspect of the world as it in fact is, must necessarily be abandoned. What we perceive at any instant is already ancient history, with the dates of the various parts hopelessly mixed.

We must add to this the difficulty of determining what is at rest and what is in motion, and the further difficulty of determining a definite uniform flow of time. It is no use discussing this matter as though, but for the silly extravagant doctrine of relativity, everything would be plain sailing. It isn't. You may be quite sure that when, after prolonged study, you endeavour to give the simplest explanation of a grave difficulty, you will be accused of extravagance. I have no responsibility for the doctrine of relativity, and hold no brief for it, but it has some claim to be considered as a comparatively simple way out of a scientific maze.

In the first place, we use the Newtonian dynamical sets of axes, and the Newtonian clock to extricate ourselves partially from the difficulties of rest, motion, and time. These have proved capable of scientific determination within the limits of our experimental accuracy. Thus the only thing left over is the choice of the axes at rest, which is a completely indeterminate problem on Newtonian principles.

Again, so far as we can at present guess by adopting the theory that all metrical influence is electromagnetic, all influences are propagated with the velocity of light _in vacuo_. This electromagnetic hypothesis is by no means established, but it gives the simplest of all possible results in respect to the propagation of influence, which we therefore adopt.

But what dynamical axes are we taking as at rest? Now our practical choice gives a range of relative velocities small compared to that of light. So except for certain refined experiments it does not matter. There are two possibilities--

(i) We may assume that one set of axes are at rest, and that the others will show traces of motion in respect to the velocity of light; or--

(ii) That the velocity of light is the same in all directions whichever be the dynamical axes assumed.

The first supposition is negatived by experiment, and hence we are driven to the second supposition; which immediately lands us in the whole theory of relativity.

But if we will not have this theory we must reject the earlier supposition that the velocity of light _in vacuo_ is the same in all directions. This we do, in fact, by assuming an ether, and assuming a certain law for its modification. Then we, in fact, adopt the first supposition so far as to hold that there are dynamical axes specially at rest, namely, at rest relatively to the undisturbed ether. Then an assumed law for the modification of the ether so alters the velocity of light that we explain why no dynamical axes show traces of motion.

I wish now to go back to the point which I made a few minutes ago, that what we perceive at any instant is ancient history with its dates hopelessly mixed. In the earlier part of my comments I emphasised the point that our only data as to the physical world are our sensible perceptions. We must not slip into the fallacy of assuming that we are comparing a given world with given perceptions of it. The physical world is in some general sense of the term a deduced concept.

Our problem is, in fact, to fit the world to our perceptions, and not our perceptions to the world.

PRINTED IN GREAT BRITAIN BY RICHARD CLAY & SONS, LIMITED, BRUNSWICK ST., STAMFORD ST., S.E., AND BUNGAY, SUFFOLK.

PREFACE.

An intensive farm is only an enlarged garden patch.

This book is not intended as a scientific book on agriculture; there are many such books which are out of the depths of everyone except professors and professionals. In a nice experiment station, nice experiments and scientific calculations are excellent; but I want to give the plain man or woman who has a back yard or back lot, out of which he might make part of a living or more than a living, a book that will show how to do it.

I want to help the man or woman who has to do the cultivation at odd times and who finds it hard to get the time for the work, even though this work enables him to do far more work of other kinds. I have had all sorts of experience with gardening, in spite of telegrams and people who want “just five minutes for some important business.” So if you have the same trouble getting the time, do not let that discourage you. We can get health, happiness and some profit in spite of the interruptions.

It won’t be enough simply to read this book; that won’t make you a gardener; but if you study it while you are working on the land and use your judgment and common sense, in one season you will be able to teach most of those whom you now have to hire as expert Gardeners at Three Dollars a Day.

If anybody sneers at your gardening as being “book farming,” let him sneer; a fool never understands what a wise man is doing: if he did, he would do it himself. You have here the plain, simple, practical facts without scientific terms—just the ordinary garden talk. There are plenty of things you will not find in this book. You won’t find analyses of fertilizers, nor how to grow “pomatoes,” or anything else that won’t sell when you have grown it. Nor will you find fairy stories of poultry profits that make the goose’s golden eggs look like thirty cents. There is a use for all that sort of thing—it arouses interest and stimulates the imagination. But you will probably be content to be a good, practical, every-day gardener who can make things grow and knows what to do with them after they have grown.

Some critics, who will not read this book, will sagely remark that such books as Mr. Hall’s are dangerous, because they induce inexperienced persons to sell out and lose their money trying to get Liberty on Three Acres or a Living from a Little Land. To repeat for such people my cautions and advice to learn navigation before buying your ship, is to blow against the North wind.

If you have skipped the foregoing, just skip again, back to it. You will see that I have promised to use no scientific terms. This book will be read by more plain people than by scientists, and so I have aimed to talk just as I would if I were trying to teach you how to raise lettuce—or rather trying to teach you to learn for yourself how to raise lettuce. For we cannot teach anyone anything, we can

only give him the opportunity of learning. So if the experimental agriculturist thinks that a good deal has been left out that might have been put in, I hope he will remember that I have had to pick from a measureless field, and by trying to crowd in too much I might easily confuse the less experienced and make it hard for him to learn.

And yet no one need think that by reading a book or any number of books he can be made a gardener. That is done by work of head and hands on the soil; and the best preparation for a really scientific use of your own land, is to hire yourself out for a while to a market gardener and get the practical, every-day experience.

You might as well expect to learn writing without using a pen as gardening without using a bit of land. You will make some mistakes and lose some crops, but I can show you how to profit by mistakes and to lose very little by losses.

If you don't understand the directions, that is my fault: I should be able to make it clear to everyone. So just write me (a pencil and a postal card will do) and I will tell you what you want to know, if I know it myself or can find out.

BOLTON HALL.

56 PINE ST., NEW YORK CITY.

INTRODUCTION.

A farm is the only proper home. Working for yourself is the only true independence. Labor on the land in the open gives health and long life. Raise a living and sell the surplus. Work all the time, but don't overwork. Make faces at the cynic who says the farmer and his wife and children work fifteen hours a day and then starve. It isn't so. Work alone is not farming; you must manage. Farming needs intelligence and care, nothing more so. Everywhere you see good farm-homes and poor ones; the difference is in the farmer. What the good farmers do, all can do.

In this book, the author tells how to lay out the land, how to prepare and plant and harvest, and how to make life joyous. He has boiled down the experience of himself and his friends and the information contained in bulletins and books and catalogs. A cobbler or clerk or typo, can take this book and with his tennis-made muscle and his trade accuracy can make a bare living the first year, a good living the second, and start a bank account the third. I know it because I helped do it in my youth and I have seen it done all my life.

One of the obstacles in the way of town families going to the country is separation from friends and going among strangers. Another is the conscious ignorance of the work and a sense of helplessness. These are real and valid difficulties. They are equivalent to the difficulties besetting a German or Norwegian farmer coming alone into an American community in a new state. The hundreds of thousands of European farmers who came to the states every year from the forties to the end of the eighties overcame this difficulty by organizing colonies of friends and neighbors and settling in one spot. They thus had society and they had the benefit of their best leaders. Then their old friends kept coming in smaller squads. This is the way for town people to do. Find six or ten or a dozen and go together. Even if all are not relatives or friends they may be of the same class or trade.

To any such colony I will furnish the money to pay for all the land they need and let them begin paying the cost price of it at the end of five years and finish in ten, with 4 per cent. interest. They may pick the tract and bargain for the price. Upon their showing that the agreed number are ready to go and are able to make the improvements and provide the working equipment, I will advance the money to pay for the land. They can divide it up to suit themselves.

I have furnished farms already plowed, fenced and housed, and horse and cow free of charge. But these empty-handed folk, who have saved nothing out of their former occupation, lack the qualities to manage for themselves and to succeed at farming. They are too helpless and dependent. Their best plan is to hire out in the country until they learn farm work and life, then rent a piece of land, and then buy.

How much land shall each one have, how much can he properly cultivate? That depends on what he raises, and this governs his location and the price of the land. With present methods, he will need 20 acres if he keeps a dairy of ten cows; or, 10 acres if he raises vegetables, small fruit, poultry and milk; or, four acres is enough for truck and a horse and cow, while one acre is enough if he raises only celery, asparagus or tomatoes. The price of land is influenced by social conditions, speculation, proximity to and quality of market and agricultural adaptability, all the way from $5.00 an acre to $250.00. There is plenty of it not above the value of the public and private improvements. It is useless to buy a farm of 160 acres for one family. They cannot work it, it is a dead

expense, they would be lonesome, would starve and quit. But a colony, settling as neighbors on well-chosen land for which they pay only when they have had time to earn it, will have every opportunity to succeed.

Only in rare cases would I advise town dwellers to go singly to the country; they are disqualified by their social and industrial habits. A colony of friends or Co-operative Associations overcome the difficulties and do in fact assure success to any one possessed of industry and frugality.

By intensive cultivation is meant, not any particular kind of product, but farming the land thoroughly, getting the best yield and the best quality out of every acre, the best seeds and the best breeds and the best way of disposing of the crop when you get it. The farm or garden may be in the vegetable or small fruit or corn and hay or dairying section. In either case, you can cultivate it intensively, which is thoroughly.

The book will tell you in A, B, C style how to farm. I am asked to tell what to do with the crop after you have raised it, how to buy what you don't raise, and how to make social substitutes for the city crowds and sights.

Associate! _Co-operate!_

You may not know it, but the world is turning from private trade to co-operation at a fast rate. In some countries most of the farmers do all their business by co-operation.

Co-operation is simple and sure and safe, when enough people want it and are shown how.

I have practiced co-operation in my business for twenty-three years. I have been intimate with it the world over for twenty-five years. I have seen it grow and grow until it numbers its millions of workers in some countries, and is doubling every five years in many countries and states. Though I am a manufacturer, my chief occupation is to preach and teach co-operation to farmers—at my own expense.

Co-operative creameries have changed Minnesota from a declining wheat state to a rich dairy state. Co-operation has saved the California orange grower from bankruptcy and made him prosperous; it has raised Denmark's exports of butter, eggs and bacon from eighteen to eighty millions a year, and it has almost cut off our supply of policemen and politicians from Ireland, because over a thousand co-operative associations have grown up there in twenty years.

After you have undertaken what this book tells you all about, you want to count on forming co-operative associations with your neighbors to do all the business that you have. You raise your own crop; but pack it, ship it and sell it through your association. You use bought goods, but buy them all through the association. That gives you a saving in expenses, a saving in price, and a better quality. What is still more, it makes better neighbors of you, and rids you entirely of the demoralizing tricks of the trade, and prevents you figuring how to get the best trade out of the other fellow. You are yourself "the other fellow." In the co-operative way, your interest lies in producing the best stuff, which will gradually improve your motives. Co-operation fits any sort of business, if there is enough of it.

One hundred and fifty cows are needed to start a cheese factory, 250 for a milk shipping association, 500 for a butter creamery; fewer than these do not pay.

For co-operation in raising vegetables and small fruits, no fixed quantity of product is required; two or more persons working together is better than each for himself.

Talk it up as neighbors and then hold a meeting. Let all who want to join, sign an agreement to deliver all their truck to the association and pay a membership fee of $5.00 or over. Each member should have an equal voice regardless of his acreage. Organize, either as a corporation or a limited partnership. Elect the best qualified men to be officers, and then give them unqualified support. Select a manager and see to the marketing arrangements. If the quantity raised is large enough, it is best to have your own receiving and selling agent in the principal market. Every member must make a legal contract with the association to submit to its rules about condition, packing and delivering, to apply to his entire crop. Good quality, reliable packing and regular supply are essential to good prices.

The manager or inspector must have full authority. Each member's delivery is graded, weighed, measured or counted and accurately recorded. Once a month the account from each grade is made up, and the proceeds, after paying expenses, are paid over.

The manager should be an experienced trucker, competent to instruct and advise about the work of planting, growing and gathering. The growers meet each other at the station, and compare notes. They all learn what is known by the most expert among them. They can arrange to have one man gather up the crops from several places and make one load to the packing-house, taking turn about in this service. Small or poor growers may be admitted with a nominal payment, even as low as 25 cents, the remainder to be paid by a 5 per cent. deduction from his proceeds.

The association and management can also fill the assembled orders of members for fertilizer, seed, implements and packing material, at wholesale prices. In time you will make your own boxes, erect a cannery for the surplus and even buy your own groceries co-operatively.

You can form a credit society with unlimited liability, to receive on deposit the members' surplus and borrow from the city. That money is lent, for productive uses only, to members of known ability and honesty, who give two similar members as security.

When you get safely started in one kind of co-operative association, you will easily go to the next, as the Danes and the Irish have done.

ST. LOUIS, MO.

N. O. NELSON.

CHAPTER I.

THE GARDEN YARD

No man knows, nor can know, the capacity of a yard of earth, for it is unlimited, just as the speed of the engine is unlimited. Just as with the engine, the only question is whether it would pay to make it do any more—it may cost too much. Where land is cheap, labor is high; there intelligent cultivation will pay, but intensive cultivation will not. That is the place where the field crops should be raised.

But the garden crops should be raised right round the towns and cities and it is foolish to get to a distance from them. Stay right where you are and get the piece of land that is best for your purpose; buy it, if you can without paying too much for it; if not, rent it for as long a term as you can; or get permission to use the bit of land, the vacant lots—there are plenty even in the most crowded cities—and raise your truck and your income on those lots. Without separating yourself from your acquaintances or exiling your wife and children, learn to get your living out of the earth.

Suppose that a man owns his house, even if it be but a bit of a bungalow, and suppose he has a little bit of land on which he can raise the most of what the family eats; he may have to work hard, especially if his family cannot help in the work, but at least he is independent; at least panics, lock-outs, change of circumstances or even loss of health will not reduce him to starvation.

If you have a farm, Intensive Cultivation should interest you all the more. Every farm is full of opportunities to make good money; but you must not make the usual mistake of half working a big piece of land; that means that you will always be overworked, always have a lot of things that you know ought to be done, but cannot find time to do; always have common grade crops that bring common prices. Everyone that is overworked is underpaid, for he cannot do his best work.

Use the big fields for pasture, or for raising fine horses, or for pigs or Angora goats or even for sheep; you had better let the fields run wild rather than half cultivate them.

Keep accounts and watch your chance to sell all the land that does not pay well. It may be that you are missing a fortune in the old neglected orchard, or in the chestnut or hickory grove. The black walnuts or butternuts, that are usually left for the neighbors' boys, may be the most profitable part of the farm.

The wood-lot may have possibilities for barrel hoops, which may be sold to the improvement of the timber. It may need only thinning to bring you a steady income while it increases in value.

Fine apples grafted on the old trees that now bear only cider apples, if properly sprayed and thinned so as to give first-class fruit, may sell for more than all the corn you can raise.[1]

The “pesky briers” that the farmer struggles with year by year, may be the raspberries and blackberries that will sell readily for good prices, when they are cultivated, to the summer residents or boarding-houses. Your exposure and soil may be just the place for the fine strawberries with which, when nicely separated from the second and third grades, no market is ever overstocked.

But if you are always behind with the work and always short of cash or worried to pull through, you have no time to think of these things and no means to hire labor nor to develop them.

That pond may be needed, if it were cleared out, for a profitable ice supply, furnishing paying work in the winter. The stream may be a valuable water-power or at least may bring a high-priced crop of water-cress; or it may be the very water needed, when properly distributed, to make yours the most fertile land in the county. The bit of swamp land, that raises nothing but mosquitoes, may need only a few dollars’ worth of cranberry sets to be the best paying acre in the country side.

There may be a veritable gold mine in a neglected quarry, or brick-clay pit, or kaolin clay deposit, or in a sand bank, or a vein of marl.

Possibly you could rent the farm house or let camping sites for the summer to people who would pay city prices for much of your stuff; so that you could afford to keep help enough to leave only the easy work of superintendence for you. Brains save more work than machines.

If you are raising the same crops that your neighbors do, harvesting at the same time, and getting the same prices that everyone else does, you may be sure that you are neglecting your chances.

The money is in finding things to raise that will sell, and that do not have to compete with all the others.

Says the _Farm Journal_: “Farmers need more time to plan their work and look after the business and economic end of their calling. The employer who makes a full hand in barn and field from 5 A. M. till 8 P. M., has no other time to devote to the real business of the farm than the hours in which Nature imperatively calls upon him to rest, and a man with aching muscles and tired limbs is not in condition to think clearly or plan intelligently. It is poor economy for a farmer to take the place of a dollar-a-day man in the field, when in so doing he has left no leisure in which to work out the details of his operations.”

Think—think—it is true that we ourselves must work with the men if we are to get the best work out of them; there is a big difference between saying “Go, do that,” and “Come and let us do this.” But it is not enough to work; any jackass can do that.

You know the old fable: “A farmer got his wheels stuck fast in a miry road. The man knelt down in the mud crying to Hercules to come and help him. Said Hercules, “Get up and put your shoulder to the wheel, I help only those who help themselves!”

(There is a new part to that fable)—Now the mire was very deep and even Hercules’ help was not enough; so he called on Pallas, the Goddess of Wisdom. Said she, “Put this lever under the wheel.” Then the wagon was easily lifted out.

Since then, some one else suggested using wide tires, so that the wheels would not sink at all, and another invented a split-log road-drag to keep the roads hard. But we are still waiting for the farmers to learn to use them.

Maybe the roses in the bit of garden would bring you bigger money, if they were made to bloom at the right time, than the potatoes that take twice as much outlay and ten times as much work.

Pick out as much land as you can attend to without walking your legs off, and raise on it the best crops that bring the best prices and let the rest take care of itself.

The market is more important than the crop. Consult the editors of your agricultural papers about where to sell. Require bank reference from any commission merchant that you do not know, and write to the bank for its report on him before you ship to him. Make his acquaintance, if possible, and talk to him about what he can sell the best; naturally, he will take more interest in the affairs of a man that he knows than in a stranger. Don’t go to town or to the boat or railroad with half a load or with a load of poor stuff. Arrange with your neighbors to take enough for them to make your trip pay.

If a trolley or a carrier can be brought into use to make regular shipments, see some merchant or hotel man and arrange to supply him constantly. Then lay out your plantings so as to have a constant supply of what he needs.

If you are choosing a farm or have a chance to sell yours, inquire and look to see if you can find one near a good market where you will earn your own commissions. The way to find out what you want is to talk about it to everyone you meet. A good local map will

help you, but of course the real estate agents know more about what is for sale and the prices and values than you could learn in a year's travel. No men, except editors and hotel clerks, are so ready to give information as the real estate agents. Remember, however, than even when they are honest (most of them are, like the rest of us, as honest as circumstances allow), the successful real estate agent must see the rosy side of the peach and may not point out the worm-hole on the other side. You will have to look for that yourself.

When you have found what you want, point out that you are buying to improve, so that the security will be better every day, and fight for easy terms and for a long mortgage. You can get the privilege to pay off any time that you cannot use the capital to better advantage.

Let some good lawyer examine the records and see that the papers are all straight, and guarantee the title. If there is a local title insurance company its policy is worth all it costs, and will help you greatly should you want to sell or to raise another mortgage.

Buy your land—don't rent it; it does not pay to put your work into another man's land.

Every improvement in the condition of the earth—agricultural, mechanical, ethical, educational, political or even religious must go eventually and mainly to the benefit of the owners of the earth; therefore get hold of a bit of the earth, so that everyone who does good will do that good for you.

Get a small bit of land near the market rather than a big bit away from it, because the more people there are near you the better you can live and the more money you can make. Besides it is much pleasanter and better for the wife and children, as well as for yourself, to be near schools, libraries, proper company, stores, than to be away out among stumps. A growing town will make you rich when it grows out your way, because you are in the way and when the land is wanted you must be paid to get out. Meanwhile, you can get manure and help much easier and cheaper than if you were at a distance.

Don't put your labor or your money into expensive buildings: they only invite the tax assessor; but get proper buildings—they may be only shacks, but they should be well planned shacks, for you must have room enough to shelter your tools, wagons and farm machines, to house your stock, to store your crops, to sprout your seeds, to save your manure and to do indoor work during bad weather.

FOOTNOTES:

[1] There is only one good way to do this: cut back all the old wood and work out a new top on which to graft the fine apple scions.

CHAPTER II.

THE SOIL.

If this book is to be of real service, we must be clear about the terms and expressions, so that, though you may know nothing about gardening when you begin to read it, you may know enough to earn a living from the soil when you finish it—and practice a little.

Many talk glibly enough about the soil, though few could tell exactly what it means. But market-gardeners must understand it, if they are to live by it. So it will be well to begin with the soil itself. Soil is that thin layer of earth that covers our globe like a blanket, and in which all that plants, beasts and men live upon, grows. If it were washed off, starvation would follow. The scientific explanation of the origin of this blanket, is, that it was formed by the action of heat, cold, water, frost, ice, low forms of vegetable life and tiny animals; sometimes working singly and sometimes all together. It is now established that the most of the face of the earth was once rock which was rubbed, crushed and ground by these forces until this surface layer was made. Then higher forms of life became possible. Not centuries only, but aeons of time, were necessary to accomplish this. Layer upon layer of finely crushed particles were exposed to the action of the air which completed the work the grinding of Nature's forces had begun.

To follow out the story of the development of the soil is a most fascinating study, and if you have time from your other interests, you will be glad that you took it up; for though you may be a good farmer without this knowledge, you will be a better one with it, because you will be more intelligent and sympathetic. The soil-blanket holds within its warm folds all that is necessary for life, and the wonder of it all increases the more we learn about the millions of years and numberless forces employed to bring it to this state of perfection. If Nature has not wearied in her great work, there is poor excuse for the gardener to shirk or neglect the labor necessary to get the best possible results from any given piece of soil.

Nobody yet knows what are the best possible results from any given piece of soil; for since new discoveries are being made every year, we can show only what has so far been done with the best knowledge and skill at our disposal. One man in Pennsylvania is selling his soil; not his crop, at $1.50 per bushel to inoculate other ground.

The fine, fertile layer of earth that is called soil does not go very deep. It covers another layer which is harder, coarser, colder than itself, and this second layer is known as the subsoil, or that soil which is under the surface layer. In all temperate climes the difference is strongly marked, but in rainless, sun-dried regions there is often no difference to be noted. The intelligent farmer or gardener has the opportunity to decide just how much of that subsoil he will convert into surface soil, and the means of doing this will be disclosed later under the head of “Tillage.” The more of it he brings into use the greater his own profit, so that it pays to know how. In the early days of farming no effort was made to bring the subsoil into use, and consequently the returns from agriculture were small. Now we know better than that, and we also know how to get more out of the soil, whether surface or subsoil.

No soil, no garden; so the new gardener must get acquainted with the ground he intends to cultivate. It is not to be denied that soil which is in good tilth will be a great help to the beginner, but that is only to be had in well-cultivated gardens, which usually bring a good price when found in the market. Besides, with proper care and attention, any well situated soil can be made to yield good returns, and the gardener who is not disposed to give proper care and attention will find nothing in this book, or in any other, that will teach him how to succeed. The German idea is that a good soil is merely a place to put fertilizers (and German ideas on gardening are not to be despised). This is simply another way of repeating that, with brains and work any soil can be made to yield good returns. It is not safe, however, to trust to the “Light of Nature” as to what “proper care and attention” is, so here are the details.

If you are already settled and are planning to use your back yard for a garden, you will have to take the soil as it is, and by your own effort make it what it should be. There is no cause for despair no matter what it may be. A back yard that was trodden almost as compact as asphalt, and whose clods when dug had to be broken up with an axe, was made to yield a large variety of flowers the first season it was planted. So go ahead and do what you can with what you have. But, if you are hunting for a garden plot, bear in mind the importance of soil texture. You may thereby save yourself both time and labor.

The first thing is to examine the soil to determine whether it is sandy or clayey, dry or moist, light or heavy, well drained or wet; whether it is warm and live, or cold and dead. You will then learn what sort of cultivation is best for your particular plot of ground.

Because in your neighbor’s garden a certain treatment has been successful, is not saying that it will give the same results in yours, unless all the conditions are the same. For instance, his light, sandy loam needs little cultivation, and your soil may be hard and clayey. In that case you would have to make up the difference by careful work.

There are “gardeners” who think it is sufficient barely to break up the ground, add a little manure or other fertilizer, and scatter seeds. That they get any sort of results only shows how willing Nature is to give a return on the slightest labor. But Nature is wise as well as willing, and therefore gives lavishly to him only, who, by intelligent labor, deserves the best returns.

Therefore, learn the needs of your soil and supply them, and you will have no cause to complain of the niggardliness of Mother Nature to those of her children who feed at her bosom.

Plants often die for lack of moisture in the soil, and this condition cannot be satisfactorily remedied by the watering-can. The trouble lies back of such surface treatment and can only be cured by getting at the cause. The soil should be so prepared by tillage that it will catch and hold enough water to supply the plants with the moisture they need even through hot, dry spells. Plants draw their nourishment through their roots to their stems and leaves, and you need only examine the fine roots and rootlets of any plant to realize for yourself that such nourishment could not be taken in in a solid form. Plants are constantly drawing this moisture from the soil and as constantly giving it off into the air through their leaves. If you will watch any plant during a drought, you will see the leaves begin to shrivel before the stems or branches show signs of suffering. This is Nature’s effort to sustain the life of the plant as long as possible. The shrivelling of the leaves prevents the escape of the little moisture the plant can draw, and retains it longer within the plant’s system.

Deep plowing, the breaking up of the subsoil, the addition of decaying vegetable matter or humus, fertilizing with stable manure, and the raising of crops that can be frequently tilled, all help to add moisture to the soil. If you do these and the dry spell does strike you hard, so that it seems necessary to bring water, the soil will suck it and hold it, instead of letting it pass off quickly through the action of sun and air. Frequent stirring of the surface soil, to the depth of one inch, will make a little dry layer or top-coat through

which the moisture does not readily escape. This is what is called a “mulch.” A mulch may also be an added coat of leaf-mould or stable-litter or any little dry covering which will prevent the moisture from escaping.

For early crops a light, sandy loam is best. A sandy loam is a loose, sandy soil made productive by good tillage, by mixing in humus and plant food or fertilizer. But when you haven’t the best, it is for you to counterfeit it as nearly as possible. The advantages of sandy loam are that it is early, easy to work, responds quickly to fertilizers and is readily kept in good tilth.

“Tilth” is really the planting condition of the soil, and good tilth means the best possible conditions for planting seeds; where the plow and the harrow have done their work; where the sun has warmed and the rain moistened; where the fertilizer has sweetened and quickened; where stones and weeds are unknown, so that the new life finds the best conditions for sprouting and developing. You will understand why such soil is not often in the market. It is Nature’s materials plus man’s intelligent labor; and he who has it, is usually found working it to his own profit.

Some soils are easily put into condition: others require much time and labor, but all always repay. It is well, however, to avoid a hard, cold, clayey soil if possible; it takes so long to warm up, that the seeds make little progress. Of course, steady persistent effort will greatly improve even this soil, and if that is the sort you have, you must do your best with it, but the average gardener cannot afford to wait.

Compared with agriculture, which has been known in some form ever since there have been any records, tillage is very new. Like many another important thing, it was discovered quite accidentally by an English farmer, named Jethro Tull. He found that by stirring up the soil about his plants, he got better returns; and gave his discovery to the world. But he could not explain why it was so; he merely knew the fact itself. Science has since discovered that it is due to the action of the air in helping to break up the many compounds found in the earth containing plant food. It was a simple thing, yet it has really revolutionized gardening. Before tillage was known the returns from the sort of cultivation in use were very scanty, and this book had never been written had Tull’s discovery never been made. So you may be able to do the world a great favor if you cultivate intelligently, not fearing to experiment or to make known the results of your experiments. It may be reserved for you, in your little garden patch, to discover some new truth that will prove a blessing to the whole world, for no science today offers so wide a field for discovery as the science of Agriculture, nor so sure a return for labor expended.

There is a story that illustrates the value of tillage. A man lay dying and as his four sons gathered about his bed he whispered feebly, “My sons, there is a great treasure hidden in the garden.” Scarcely had they laid the body of their father away, when the sons went to the garden and began digging it up. They dug every inch carefully, and found nothing for their pains. Then the eldest son, being of a practical turn of mind, suggested to his brothers that they plant the garden and thus secure some return for their labor. This they did, and when harvest-time came the returns were so wonderfully increased that they said, “Now we know what our father meant. Let us seek like treasure in all our fields.” And in every garden and field lies hidden the same treasure that can be revealed only by the expenditure of intelligent labor.

Tillage is an art in itself, and very important to success. There are two kinds—the tillage of preparation and the tillage of maintenance. They are widely different in their purpose and effect. The average farmer thinks that both may be carried on at the same time, and this belief may be in part the cause of his failures.

The tillage of preparation includes not merely the breaking up of the soil by the plow, but pulverizing it for as great a depth as the roots of the plants will reach. How deep that may be, depends upon the character of the soil and of the crops. For example, a hard soil with a subsoil near the surface, must be plowed deep; so that the root crops, which run deep, may find sustenance. On the other hand, sandy soil, or one which leaches away, can stand only shallow plowing, as we must hold the subsoil firm to prevent leaching. So that, even in the tillage of preparation it comes back to the same point, to learn the needs of your particular soil and supply them.

The tillage of maintenance should be given as often as once a week or ten days, and is merely that surface loosening which enables the soil to drink in the rain and withstand the heat of the sun. The loosened surface will not cake about the plants, and it makes a layer of mulch for the protection of the under soil.

By the addition of humus, or vegetable matter, a clayey soil may be put in condition so that it will respond to further tillage as satisfactorily as the lighter, sandy loam. This is the way to “counterfeit the best soil.”

Humus is added by plowing into the land vegetable matter which is in condition to rot quickly and become thoroughly mixed with the soil. Rye, clover, cornstalks, vines or other garden waste, and manure, are commonly used. Manure that contains a large proportion of stable litter and sweepings, and street sweepings, are especially rich in humus, and are much sought after by experienced gardeners. By adding them, the texture of the soil is lightened and improved, made loose and mellow so as to hold moisture, and is at the same time prevented from caking. Moreover, humus contains plant food and heat that make seed sprouting easy.

The amateur gardener seldom recognizes the importance of the physical texture of the soil, but the best results demand the best conditions. Unless you want to grow pears and plums—which thrive in clayey soil—break up the clayey earth and improve its texture in every way. Your garden will repay you, and you won't go about denouncing those who have written books about the possibilities of small areas as wilful deceivers of the guileless and unwary. Get it firmly fixed in your mind to start with, that, if your garden does not yield adequate returns upon your labor, the fault is yours. You are working unintelligently, and deserve no more than you are getting. To know your soil is to be able to give it the treatment it needs to make it fruitful.

CHAPTER III.

SOIL FERTILITY.

Soil fertility is the power in the soil itself to produce a good crop under proper conditions. Man can neither make nor destroy the land. All that man can do is to make it more or less efficient, according to how he uses it. Two men may take two pieces of soil of equal fertility and get vastly different results; by careful study and experiment we may learn how to take advantage of this fertility; but the real secret of it, Nature has wisely locked up in the soil itself, so that one generation of men cannot really rob the next. It has been said that old-time farmers, of New England particularly, robbed the soil of its fertility, so that their sons have been compelled to abandon the old farms and seek new land in the west, or new occupations in the cities of the country. The real truth is, not that the soil has been robbed of its fertility by the fathers, but that the sons have continued the unenlightened methods of the fathers even after their ineffectualness has been proved.

Since that land was abandoned it has not really been idle. Nature has been improving it all these years by placing leaves and trees back upon it, thus providing humus; and also by the action of heat and cold. Some of this land, overgrown with briers and brush, has been cleared and found to be better and stronger than ever before. Much of the soil is sour, but that is easily remedied, and wherever a patch is burned over, the grass works in well. On some of these abandoned farms there is an excellent opportunity to combine intensive culture on the lowlands with orcharding on the hills, for the fertility is still there. If man could destroy this quality, that clings to all soil, he would have spoiled it centuries ago, and the race would have starved. But we are a long time learning how best to use it.

Robert S. Seeds, of Birmingham, Pa., thinks he has solved the secret of unlocking that soil fertility, and he offers the astounding results of his operations on an abandoned farm, as proof of his claims. He not only raises enormous crops, but he sells his soil by the bushel, to his less enlightened neighbors to inoculate their farms. He tells the story of his experiments in a lecture called "How God made the Soil Fertile," which is published in pamphlet form and sells for 25 cents.

He says "The Lord made all the acres of the land fertile, from the Atlantic to the Pacific, and gave it to man to live upon, to prosper and be happy. In doing so He never hauled a wagon-load of manure or a load of lime, nor bought a ton of fertilizer—and how did He do it? He did it with vegetable matter; and I thought if the Lord could do it, I could do it. This sounds a little conceity, but I mean it."

As a result of this belief, Mr. Seeds took to experimenting, beginning with the crops that store nitrogen in their roots, such as crimson clover, and with purple-top strap-leaf turnip. But the results were not sufficiently great to please this man, who was after all there was in the soil. He needed some plant with longer roots, and finally hit upon the cowhorn turnip, which will grow roots from 9 inches to 2 feet long, thus making available the plant food locked up in the subsoil. Finally he combined cowhorn turnip and rape, and now his soil is the most fertile in his district, and is so profitable as an inoculator of other soils that he keeps fields free from harvest crops so as to have the soil for sale.

"Bob Seeds" further says that a field filled with the decayed vegetable matter and humus from one crop of crimson clover plowed down, will hold fifty tons more water to the acre than soil that is not. If you figure how much water you must have to raise a crop of corn, oats, potatoes, hay, etc., you will see the value of land that has the power to hold water. There was a farmer in Pennsylvania

who got his farm in such a water preserving condition that he said the spring rains were a nuisance. Watch the soil and you will see, that soil that is filled with decayed vegetable matter and humus is warmer in the winter-time, cooler in the summer-time, wetter in dry weather and dryer in wet weather.

A mulch which preserves the moisture in hot or cold weather also unlocks this fertility of the soil.

All of this is of immense importance, not only to the farmer on a large scale, but also to you, with the limited area of your garden yard; for in it lies the secret of heavier and earlier crops than your less instructed neighbors. Professor Whitney, Chief of the Bureau of Soils, Department of Agriculture, Wash., says that deep plowing and shallow cultivation are the best means of retaining moisture in the soil, and he adds, “Strange as it may seem, while we suffer if we do not get rains, we should actually be better off, as they are in the arid regions of the west, if we did not have any rain during the growing season and had a means of providing water when we wanted it. The trouble with us is that we cannot maintain the dry mulch, because we have rain on the average every three days. If you knew what was coming, you could save your crop through any ordinary period of drought, provided you had the skill, the judgment and the chance which would lead you to begin your operations at just the right time.”

According to Professor Whitney there are about 400 distinct types of soil so far encountered in the United States, with varying degrees of known fertility, and only eight or ten staple crops growing. This, of course, does not include the special crops like celery; it is the regular, staple field or garden crops that are unnecessarily limited. These are grown on all kinds of soil in all parts of the country without regard to the suitability of the soil to the crop.

The Government, through the Department of Agriculture, has given a great impetus to plant introduction, and you cannot of course expect to rival or approach it, with its enormous funds and staff of experts, but you can experiment with the new crops it introduces. Hitherto, in this country, where the soil was too dry for corn or wheat, or too moist for potatoes, it has been neglected altogether; but the present movement includes finding crops suitable for these lands. The Government has introduced the durum wheat which yields crops in regions suffering from drought, and in 1905 the United States exported 6,000,000 bushels of it; Japanese Kiushu rice is doing well in Louisiana and Texas rice fields; the Japanese salad plant, the udo, is being tested from Maine to California and giving good results; Kafir corns from Abyssinia, India and East Africa are being grown in Kansas and other western sections; while the English broad bean, Hungarian paprika, and fruits from all parts of the world, are being tested in all sections of this country. Those 400 different types of soil should mean limitless diversifications of crops, and it is fair to assume that the real day of agriculture, in this country at least, is only just dawning.

The Government is now testing profitable crops for the farms of New England which have been abandoned to the mortgagees. Areas there are too small to grow corn[2] and wheat in successful competition with the great farms of the west, but there are other crops which will yield even better results and command the market. You, who are now coming into the great calling of earning your living from the soil, could not have chosen a better moment for entrance. Keep in touch with the Department of Agriculture. It is your department, a sort of college or training school which you maintain, and anything you want to know the Department will gladly try to tell you. If you want to know what is best for you to plant on your patch, send a sample of your soil, tell where your farm is located, what are your means and experience, and the suggestions made will fit your particular case. If you send any of your requests, whether for advice or for bulletins, addressed simply to the Department of Agriculture, Washington, D. C., you will get a reply, and will find out who is the head of the special department your request was referred to. The Department is doing needed work, and by corresponding with them and getting advice, you can give proof of your interest.

FOOTNOTES:

[2] NOTE.—But corn growing is on the increase in New England and at the great Omaha Corn Show a Connecticut farmer won three first prizes. The Flint varieties are especially adapted for the New England climate and soil and open up new possibilities for the New England farmer.

CHAPTER IV.

LOCATION.

How to buy land and why; how to help the poor to keep themselves on the land and what plain people have actually done; the record yields and how they have been raised; how much capital can be used by one man, are considered in “A Little Land and a Living.”

How much of a crop you may be able to get; how much or rather how little capital it takes; how much labor is needed; where cheap lands are to be found and how to clear wild land and how to build, are all treated fully in “Three Acres and Liberty,” now published in fine shape at fifty cents. So this “hand book” need only show what other things are included in the term “location.”

If you are thinking of the character of the soil when hunting for a garden plot, you will more than ever think also about the importance of location. Any soil, even the best sandy loam, needs some fertilizing and watering, and you cannot afford to use land where manure can not be had easily, or where there is not a good water supply. To pay high for fertilizer cuts the profit from your small area, and this is more especially true if your soil is clayey and needs much preparation-tillage. In most cities you will find stable-keepers and others who will give you manure or street sweepings in the winter in return for hauling it away. That is a great advantage to you, but if you locate your garden where truckage amounts to two or three dollars a load, you have offset the advantage you derived from the free manure. Also, if your water supply is poor, you will find it difficult to carry your crops through the hot weather.

MARKET.

You can raise a good crop from good soil properly fertilized, but if you cannot market it to advantage, you can’t sell it at a profit. A long railway haul not only injures the garden truck, but it also eats up the profits. Therefore, get your plot near a town or city where the expense of selling is reduced to a minimum and where the demand for garden products will at least equal the supply.

So the good-garden-plot tests are three: first, the character of the soil, second, the location as regards the market, and third, the demands of that market. He who must of necessity use the land where he is, will, if he uses his brains as well as his hands, find his reward satisfactory, even though it fall below the returns from a plot with all advantages.

CHAPTER V.

SEEDS.

The expense and labor of preparing and tilling soil is too great to allow you to plant poor seed. The stock-breeder does not take his sickliest, poorest specimens for breeding purposes, but rather selects the best and most nearly perfect specimens; you should be careful to do the same with your plants. The farmer’s work is just as important as the stock-breeder’s. It should be the aim of each to improve the strain and produce the best possible result. Therefore, if you are growing corn, plant seed only from the stalk that produced the most and the best ears of corn. It is good to send fine ears to market and get the best price for them, but if you save only your scrubby ears for seed, next year you will not have fine, perfect ears of corn to send. So select of your very best for seed purposes, and if your best is not good enough, then buy from a better grower who has the best. Aim to produce an ideal ear of corn. It can be done, and you might as well do it. Only in this way will you find your corn crop paying you for your time and labor. If you carefully follow this every year, you will find your acre annually producing more and more corn without any additional labor or expense. That is one trick in making farming pay. It is a trick that holds good with every garden crop as well as with corn. It won’t do to wait until harvest time to find out if the seed you have planted is any good, if you have to buy your seed and want to make a profit from your garden the first season. This simple method of testing seeds may save you time and money. Get your seed early in the season, select about one hundred and put them between two moist pieces of flannel, which in turn are placed between two soup plates. Keep the flannel moist (not soaking wet with water standing in the dishes), and as soon as the seeds have sprouted, count the proportion of live ones. If only a few of them have sprouted, you will know that you cannot afford to give ground up to the use of such poor seed. The larger the proportion of your test seeds that sprout, or “germinate,” as this process is called, the better for your profit, if you plant from this same stock or assortment.

Be sure you deal with a seed house that has a reputation at stake; and if possible go there yourself and see the man who really knows about seed: generally there is only about one man in a concern who does know his business.

If you answer attractive advertisements and buy at “big bargains” you may lose your money, or, what is worse, you may be kept waiting from day to day till your planting days are over, or worst of all, you may plant poor seed. The dates of planting given throughout this book are for the latitude of New York. In Northern New England planting should be about three weeks later. All the middle western states can be figured the same as New York: but all states south of Pennsylvania may be figured twelve days in advance for every one hundred miles southward.

This holds good for sowing out of doors or for transplanting out of doors. For starting seeds in your home, these times will do for the entire eastern states.

CHAPTER VI.

PLANT-BREEDING.

Plant-breeding is producing plants adapted to particular conditions or requirements; but the mere production of something new or different, is not true plant-breeding. The plant breeder has a definite purpose or aim in mind, and this comes only from a clear idea of his business. The professional breeders produce the races or groups, but the intelligent individual farmer adapts them to his own conditions, and may make modifications of inestimable value to other farmers.

Good farmers have always been plant-breeders, even though they did not know it. They have always kept the best ear of corn and the best potato for seed. They have followed the stock-breeder's plan—only the best stock for sires and dams. So no common plants should be used for seed; only the finest is worth planting. Improvement is made by selection, as Darwin taught us many years ago, but we are slow to learn new lessons. We know that we do not look to the children of physically, mentally or morally deformed persons for our specimens of physical, mental and moral manhood; nor to the cur's litter for the best type of pup. Now we are learning that the same holds good with plants, and that the farmer who keeps the small potatoes for seed will produce poorer potatoes than he ought to have.

The other day I found a farmer harvesting a measly lot of corn. "Where did you get that seed?" I asked. "Oh," he said, "I picked it up 'most anywhere." I could have told him that myself without asking.

Selection and breeding are not the work of experts alone, for any one who gains the simple knowledge that enables him to recognize the plant or crop that resists prevailing diseases and flourishes best under his conditions, needs only to preserve the seed of such plants for propagating. Cross-breeding, on the contrary, is expert work, but new strains may be secured by straight selection of individual plants, and this gives enormous results. If one persistently saves the seeds of those plants that best serve his purpose, he will soon have crops that are superior to any that he had before. The process is so simple that anybody can do it. We have talked for years of the "survival of the fittest," and this is but helping the best to beat the poorer ones.

What causes the variations that make selection possible nobody yet knows; but we do know that changes in soil, climate, methods of growing and in other things have an effect. Some variations come from "crossing," and some from no cause that we can see: in those cases they are called "sports" of nature; learn to look out for them and when the new variety is better than anything you have before produced, save it for seed and see what comes of it. You may thereby be doing all mankind a service.

CHAPTER VII.

PLANT NEEDS.

Plants need water, air, food, light and warmth just as animals do, and it is wonderful to study the shifts and contrivances to which they resort to get these, and also to protect themselves against too much of any of them. If the plant were not able to change itself to suit the conditions, it would often die where now it fights successfully.

Nothing affects the plant like the water supply; the size of every part of the plant is increased by plenty of water. It not only helps the growth of flowers and fruits, but it even changes the character of the plant. In a moist air, cactus will put out leaf-like organs, gorse will grow leaves instead of thorns; while where the water supply is very scanty, the potato will put forth no leaves, but will become like a cactus.

Yet plants do not grow in soil that is too wet, because they need air, and too much water suffocates the roots. By proper irrigation—which means giving just the right supply of water—both the quantity and quality of the crop can be improved.

While plants need light, all varieties do not need the same amount of it. You will find that those which need much light can turn towards it, and this of itself will show you where such plants should be sown. Plants have various ways to resist the supply of light when they are getting too much. They droop their heads or close their leaves, which prevents evaporation.

Different plants need different food and the same soil conditions will not suit all. Some require rich soil if they are to flourish, while some do better in poor soil. On the whole, plants, like people, are better for under-feeding than for over-feeding. In general, starving a plant makes it flower and fruit more quickly, but less abundantly; while over-feeding helps to make much stem and leaf instead of fruit, and also produces monstrosities. Too much nitrogen, especially, makes too much stem and leaf, though nitrogen is one of the most important plant foods. (Bailey says too much nitrogen can be corrected to a certain extent, by potassium put in the soil.[3])

We are sure of only three plant foods—potash, phosphoric acid, and nitrogen. Then there are lime, stable manure, green manure, clover and cowpeas to doctor the soil with, when it is suffering from chemical ills. This gives some idea of the vast unexplored regions of agriculture which afford you and every other worker in the soil an opportunity to make some great discovery for the benefit of the world. No other calling offers such limitless opportunities.

Lime is especially valuable for plant food and also to make other kinds of plant food available. Crops often fail in soil where there is plenty of plant food, because it is not in the form that the plants can use. Lime hastens the decay of vegetable matter, sweetens sour soil, and greatly improves the texture of clay soils. Besides this it counteracts magnesium in the soil and destroys its bad effects. But lime may not be applied carelessly, because, although some plants cannot live without it, some require a very small quantity. (It is, therefore, wise to send a sample of the soil, to write what we want to grow, to the nearest Government experiment station, who will probably suggest what could be done with it, to make it productive.)

The right degree of warmth is another plant necessity. The best temperature for plants generally is 86° of the ordinary thermometer (30° Centigrade). This, however, depends upon the plant. The “best temperature” varies with the species and variety. Usually, if the soil is hotter than that, growth stops, and if the greater heat is kept up, the plant dies. When the temperature is lowered, growth ceases before freezing point is reached. Some few plants may be frozen without injury if they are allowed to thaw slowly, but most of them are easily killed by the frost. Too great heat or too much cold acts the same as lack of water; the heat causes too great evaporation, the cold prevents the roots taking in the water.

Shingles stuck in the ground on the sunny side will serve to protect young plants from sun and rain, while cool soil may be had by using the shady places, or by sheltering the ground with flat sheds the roof boards of which have open spaces between them as wide as the boards. This is done in some southern tobacco fields.

It is the law of nature that living cells must have a constant supply of oxygen, that is why a tar wash sometimes kills plants by cutting off the air supply. In the same way, too wet soil or too hard a crust smothers the roots and the plants die. The surface soil should be kept loose and sufficiently dry, so that the air can circulate. If this be prevented, the soil becomes hard and sour and unfit to feed plants.

It is of the greatest importance to keep the soil open and loose by proper tillage, so as to make plants healthy and vigorous.

Though plants need air they should be protected from draughts and sudden blasts of air, whether hot or cold. For this reason, the intelligent gardener will consider the effect of wind upon his crops and where necessary will plant windbreaks. If you look about you, you cannot fail to see the ill effects of strong winds in the odd shapes of forest trees; and in badly arranged gardens you will find the same effects in the fruit trees and small fruit bushes and in the stunted crops. Plants shape themselves to their surroundings, and the way they shape themselves is determined by inherited qualities; so it may be said that the success of the plant depends upon its surroundings and upon the seed it came from.

FOOTNOTES:

[3] NOTE.—In regard to muck soils, it is not a case of excess of nitrogen but lack of potash which makes potash valuable for such. Samuel Fraser.

CHAPTER VIII.

CROP ROTATION.

In agriculture on a large scale the difficulty is how to arrange the farm business so as to make it pay. It is only of late that we are beginning to understand that agriculture is a business, and that to make it pay one must apply business principles. The best farmer is not necessarily the one who knows the most “Science,” but the one who is able to fit his science, his facts and his business in together.

The market value of special crops is so high that the grower can afford to provide the extra manure and other expensive materials to keep the land in good condition. This is the chief reason for the use of great quantities of stable manure in market-gardening, far greater quantities than are needed for mere food of the crops. So if you find that you are advised to use more manure on your small plot than some farmer you know uses on his big field, do not feel that you are being imposed upon. He could not afford to use so much and you cannot afford to use less. The farmer on a large scale has to let part of his low priced land rest in clover once in a while. You cannot afford to let any of your small area rest, so you must make up to the land by giving it plant food enough.

In these days machinery has made so many wonderful changes in the management of crops that the farmer who sticks to the old farming customs has no chance of making more than a living. When the country was new, it was the practice to farm one section until it was exhausted, and then to move to fresh soil. The farmer was saved the bother of cultivating, as virgin soil needed practically only to be planted to bring forth a good harvest. But conditions have changed and the virgin soil left today is not important in the farming possibilities. Therefore, we have had to look for other means of getting crops and making every inch of land do its share. We no longer allow land to lie fallow that it may rest and renew itself. We renew it by fertilizing and by rotation of crops. Crop rotation is very valuable because it is a saving of fertilizer and labor, and keeps the soil in good condition. This has been proved by experiments made without manure, depending entirely upon rotation for fertilizing, which gave excellent results.

There are probably a dozen or more good reasons for the value of crop rotation which have not yet been discovered and formulated, but the following are well known:

Some crops tend to correct the faults of others. It has been proved that the continuous growing of one crop injures the soil in some respect, and the crop falls off both in quantity and quality. Rotation tends to overcome this difficulty. Then, too, this rotation works out and evens up the inequalities of the soil, partly through the different treatment required by the different crops.

Different plants draw different portions of food from the soil and at different times. By rotation these heavy drafts on the plant food do not come at the same times, and the seasons get a chance to even up the inequalities.

Different plant food gets mixed into the soil, so that the roots can feed on it, by the decay of the parts left in the ground or which are plowed under. But the greatest benefit comes from the nitrogen compounds through growing plants, such as cowpeas, crimson clover, etc.; these “leguminous” plants have little knots or tubers on their roots with the mysterious power of gathering the free nitrogen out of the soil or air, and turning it back again to the soil in condition to be used by other plants. Now nitrogen is the hardest to keep and the most expensive of all the plant foods that the farmer has to buy, and to get this nitrogen is sometimes the only reason he has for buying chemical fertilizers.

This shows the importance of leguminous crops to the farm. They supply this nitrogen at almost no cost, or at a profit.

Some plants have more power than others to use the contents of the subsoil, and may draw less on the upper soil, and further, by their decay may add richness to the earth. Most legumes have this power to take nourishment from the subsoil.

Well-planned rotation helps to maintain the supply of decayed stuff in the soil, on which the plants feed. It also improves the soil’s texture. Moreover, it not only lessens the necessity for much chemical fertilizer, but it puts those fertilizers to better use. Where live stock is kept, crops should be raised to feed the stock to make manure.

Rotation is, also, a plan for cleaning the soil. Different weeds and insects grow after different crops and the succession or “rotation” as we call it, prevents any kind getting a secure hold.

It enables the farmer to meet the demands of the market, by continuous crops.

CHAPTER IX.

WEEDS.

It is not enough to know what to grow, you must also know what not to grow for profit, in a garden patch; and first in this class come weeds. Study them until you know even their seeds. You cannot expect to get rid of weeds until you know the nature of them and the best way to attack them, so that they may be readily destroyed. If you run across any common ones that you cannot place, send sample to the Department of Agriculture. They will tell you all about them. Get from the Department Farmer’s Bulletin 28 on “Weeds and How to Kill Them.” All this will pay.

One of the most common of the weeds of the north is the pigweed. This is the growth of one year and can be destroyed by simply preventing it from running to seed. A year or two will clear out even the most obstinate growth of pigweed.

Mustard, plantain, chess, dodder, cockle, crab-grass and Jimsonweed are the most disagreeable of the common weeds. The best time to kill them is when they are small; therefore, you should keep the ground constantly stirred up that the young weeds may not have a chance to get a firm hold of the soil. If they do get a start on you, don't let them ripen. Cut them down before they run to seed at all. Never let up in your war upon them. That advice holds good for all weeds, whether they be annuals, which die every year, biennials that last for two years, or perennials that can stand the winters. The biennials commonly found are wild carrot, thistle, moth mullein, wild parsnip and burdock. These are best destroyed by cutting the roots below the leaves with a grubbing hoe or spud. Be sure they are cut low enough, else they will branch out and make new seeds.

Some weeds live more than two years and are called perennials, such as many grasses, dock, Canada thistle, poison ivy, passion-flower, horse-nettle, etc. The best thing to do with them is to dig them out and take them away. Crude sulphuric acid applied to the soil kills them, or they may be starved by covering them with boards or with layers of straw. If they come up through the straw, lift it up a bit and let it fall again. There is yet another method, and if you have the time and land to spare, you will find it a good one. Smother them out by a dense growth of useful plants. Some use buckwheat and others cowpeas. The cowpeas are to be preferred as they enrich the soil by the nitrogen their roots gather. And that is another story that has its own time and place. Just now we are considering weeds, and you will find that they will keep you considering most of the time, for the only good thing so far known about them is, that they make even lazy farmers till their crops, if they have any. Left to themselves, weeds shade the crops, steal their nourishment, waste moisture, and probably poison the soil. Not even a mortgage can eat up a farmer's profits like weeds.

CHAPTER X.

INSECTS AND DISEASES.

The wise gardener uses the spray to prevent disease and the attacks of insects, instead of waiting to fight them after they have arrived. But if they attack your garden you must fight them intelligently and without ceasing.

The destruction by insects, is, generally speaking, easily seen, but diseases of plants are not so plain, and have only been carefully studied even by experts during the past fifty years. At present, all we know is how to fight insects and diseases by different substances, put on or about the plants. As fresh discoveries are constantly being made, we will some day get rid of all these difficulties. It is always better to get the advice of an expert when insects or diseases become troublesome.

Anything in the soil or surroundings of your garden which interferes with the plants during the growing season, weakens the crop and lays it open to attacks. Plants are like children. If they are badly fed, poorly clothed, ill housed or neglected, they are far more likely to become diseased than if they are kept in a good state. So look after your drainage, the character of the soil and the sort of cultivation you give it. All these help the crop to withstand disease. On the big western wheat fields, it has been found that drainage has a most marked effect upon blights, wilts and rust. Undrained wheat sections suffer greatly from rust.

Just how diseases are caught by one plant or section of a garden from another, is not fully known, but we know that insects often carry infection from one to another, as in fruit trees to which bees go for honey. The bee, coming from an infected tree to a perfectly healthy tree, may bring with it the germs of the disease or the eggs of the pest. Many scientific men now hold that plant diseases are transmitted by germs, which are carried not by insects only but also by the wind and the water in the soil.

The wrong use of fertilizers or barnyard manure may often induce disease, simply because the unbalanced food supply causes irregularity in growth, which weakens the plant's resisting power. What is called a "balanced ration," is of the utmost importance to plants. It is not enough that the soil contain an abundance of some of the elements of plant food, but that it contain all of them in nice proportion, so that the plant can draw all it needs, and not be overfed in some ways and underfed in others. That is why we add humus, why we fertilize, why we cultivate, and why we take note of our plants while growing. Only in this way can we supply their wants.

Weeds spread diseases and we should be ashamed of them. Not only are they usually favorable to the growth of insects, scales and blights, but some kinds of weeds actually breed these parasites. Moreover, they rob the soil of nourishment during the dry, hot spells, thus bringing about various kinds of rots and mildews. And now it is supposed that they give out a kind of poison, or

excrement, which renders the soil unfit for crops. All this shows the necessity of clean cultivation if we would help our crops to resist both insects and diseases.

CHAPTER XI.

RE-SOILING.

There is a good deal of talk these days about re-soiling, but the word is misleading. We cannot re-soil this earth or any part of it. The soil is there for keeps. It was here before us, and will remain after we are gone. All we can do is to put back into the soil some of the vegetable matter of which we have robbed it; and this is really what we have in mind when we speak of re-soiling. People have the habit of coining almost meaningless words, and then wondering why everybody does not know at once what they meant to say.

What we are after is, to put humus, which is really decayed vegetable matter, back into the soil. Then that natural fertility, of which we have been talking, will have a chance to get to work.

[Illustration: WINTER RESIDENTS IN A SUMMER CAMP.]

Now, decayed vegetable matter is part of what makes up stable and barnyard manure, street and stable sweepings; but, in practice, this does not afford enough humus: that is one reason why crops of clover, cowpeas, velvet-bean, buckwheat, etc., are often grown only to be plowed into the ground in the fall. These are the green manures which decay and become a part of the soil before the next planting season. Soil fertilized in this way will be richer, moister, darker, than soil fertilized solely by stable manure or commercial fertilizer. Soils that contain enough plant food to supply crops for a thousand years to come, are often barren or yield but a niggardly crop. This may be because they lack humus, which is the key that unlocks the store of plant food in the soil, and makes it available for the seeds and tender rootlets. How much more humus may do, we do not yet know, but every year fresh discoveries are made, and if we are to be benefited by them, we must get ourselves ready for the new truths by using those already known.

On his famous farm in Birmingham, Pa., “Bob” Seeds plows his cowhorn turnips, tops and all, into the earth in the fall, and by spring they have decayed. He says wherever a turnip has rotted, you can see the difference in the color of the soil even some distance away, and the abundance of the next season’s crop shows how quickly Nature responds when we work with her.

All vines and garden waste may be used for humus if plowed into the ground in the fall, unless they have been infested with insects or troubled by diseases. It is well established, that insects and their eggs manage to live over the winter by the aid of vines and refuse left lying about, as well as by weeds that the careless farmer has failed to destroy. It is well to cut all weeds, not only those that bother you in your garden, but also those that grow along the road, as often their seeds are carried by the wind or the birds into your garden patch. Gather them into a heap and burn them, adding to your bonfire all the sickly, dead, diseased, or insect-ridden vines and plants, and completely destroy them. You may be sure that the bugs on those particular plants will not bother you next year. What you lose in possible humus by this practice, you can make up by growing green manure, or even by buying some of the prepared humus materials now on the market.

The _Long Island Agronomist_, in a recent issue, tells of one of these materials which comes from New Jersey, and consists of innumerable rootlets, leaf-fibres and vegetable matter of all descriptions. It is gathered from the peatbogs of New Jersey and is really the wash from mountains and hills carried down by streams in freshet times, until some level was reached where this deposit was made. When spread on the land or mixed with the earth, it is found to hold much moisture, for each particle swells up as if it were a sponge, and the crops planted on soil treated with this preparation do remarkably well. It was so very expensive at first as to be almost prohibitive except for very valuable crops, but the price is now such that many a man can afford to use it, especially if he cannot afford the time or space to grow his own green manure.

Nothing looks nicer about a house than a green lawn, with smooth-cropped, velvety surface, but nothing is harder to maintain after a few years of cropping. This is because a well-kept lawn is carefully raked after each clipping, and is kept free from falling leaves or other vegetable waste matter. It must be admitted that the general effect is better, particularly when the lawn stretches from the front of the house to the roadside. But the lawn is, nevertheless, being starved, and though watered every day it cannot keep up its velvety surface indefinitely, unless supplied with the food it needs. This is Nature’s own secret for replenishing the earth with good crops, and all you need do is to observe what is going on around you, to find daily proof of it.

To quote Mr. Seeds again: “Every two years, we ought to sow clean blue grass or lawn grass seed over the lawn. I prefer to mow often and leave the clippings on the lawn. It is the blanket and vegetable matter that will do the lawn good. Every few years I cover the lawn with barnyard manure, in the fall; let it lie there all winter and that which we rake off in the spring we put on the garden. This is a little trouble, but I want to say that I made more money creating my lawn than I ever did in taking a fat ox from the stall, or a bushel of potatoes from my cellar.

“A man will stand on the public road in front of my place, and give me more for my property on account of my lawn; but money is not the only thing in the world. The lawn makes the boys and girls want to stay on the farm. It is on our lawn that we spend our spare moments on Sundays, entertaining our friends, in the summer; and there, beneath the shade of ‘the old apple-tree,’ the smoke curls more beautifully from my chimney than from any other I ever saw.”

So there is no reason why you should not have a good lawn, as well as a good garden, if you will supply what the grass roots want. And it is true that the lawn is a genuine asset. The man who is too busy to bother with making a lawn, or to sit on it with his family in spare moments, even though it takes a good deal of contriving to spare those moments, is the man who, by and by, is going to complain that his boys and girls have left the old place, and that “farming is mighty expensive with all hired help.” Unless you have made yourself and your family happy, you will not have achieved success, no matter how much wealth you may get. Give your crops and your children what they need for their best development, and you will find nothing to complain of either in parenthood or in farming.

CHAPTER XII.

HOW TO WORK.

If you are only just beginning to experiment with gardening, and feel that a fresh supply of fruits and vegetables from May until Christmas would satisfy you for the first year or so, you will find a plot 100 × 200 feet quite large enough to feed your family and a little more besides. If your plot has not been used for a long time, you will have to do your plowing, if you can, the fall before you plant it. This will give the frost a chance to sweeten the soil, and it is very likely to need a good deal of sweetening. Most yard soils have become acid, and in an acid soil little will grow. It comes from the earth having been so long packed down that the air has had no chance to circulate, and fresh air sweetens your soil just as it does your house.

It is not good to put stable manure on an acid soil. What it wants is a little slaked lime or plaster, to help the sweetening process. Some scientists claim that we can find out whether or not soil is acid by the use of blue litmus paper, which you can get at any druggist’s. Open the soil to a depth of six inches and put in the litmus paper, drawing the earth close up to it. Examine it in 20 minutes, and if there is any acid present, the paper will have turned red. This test is still being experimented on.[4]

If your land is in proper condition to manure, use about twenty-five heaping wagon-loads to the acre before plowing in the early spring, and then use a disc or cutaway harrow until you have made the soil as fine as dust. Then you have good planting conditions.

How much of the discontent with farming and gardening may have arisen from the old method of planting in beds, it is hard to say. But that cause for dissatisfaction no longer exists. We now plant in long rows far enough apart to allow the use of the wheel-hoe in cultivating the large and small plants alike, without having to readjust the blades. The wheel-hoe is one of the most useful of farm tools, and has done away with most of the back-breaking work of hand-weeding.

We cannot use the wheel-hoe on beds; that is why we now plant in rows. If your plot allows rows one hundred feet long, you will find one row of any vegetable enough for family use. Let them run crosswise of the slope of the ground if your patch is not level, else the rain may make channels of your seed rows. If possible, choose a southern exposure for your garden; because this gets all the sun, it will be earlier than less favored exposures. Lay out a plan of your land and work with a definite purpose. The “rule of thumb” is no more satisfactory in gardening than in carpentering.

If the slope of your land allows it, run your rows north and south, so that each row may get the sun from the east in the morning, and from the west in the afternoon. Put asparagus, rhubarb, sweet herbs and other permanent vegetables in a row at one side, so they may not interfere with the plowing of the rest of the garden.

Plant vegetables of the same height together, so far as the tillage required will allow. Put the tall ones at the back, so as not to shade the others. If you have a hedge, a building or a strip of woods as a windbreak on the side where the wind blows worst in

winter, you will get vegetables a fortnight earlier in the spring, and probably a month later in the fall. The more protected the garden, the warmer the soil, and warm soil means quick and abundant returns. That is one reason why we use so much manure. It warms and quickens the soil.

Plant vegetables that ripen at the same time as near together as their size, habits and tillage requirements will permit.

Practice rotation; for instance, lima beans should not immediately follow string beans or peas. As far as possible, keep the plants subject to the same insects and diseases together. It is easier to treat them, and besides, it leaves the other portions of the plot uninfested, if they get so bad that you have to change the position of the plants.

If you are growing fruits, you could plant a row of apple trees about fifteen feet apart on the northern border, plums and pears on the west, and cherries and peaches on the east side. Then if you could put a grape-trellis next the apples, and a row of gooseberry, currant, raspberry and blackberry bushes in front of the grapevines, you will have a windbreak as a protection against the north winds, which will prove profitable in itself as well as in its service to the vegetables.

Transplant freely; nearly all vegetables are the better for it, especially lettuce and other salad plants. Sow seed thickly in the first place. You can easily thin out or transplant, but you cannot increase the number of plants if you have sown thinly. Even a small proportion of weak seed that would not sprout would seriously affect your crop. Besides, where you sow thickly, you can afford to weed out all but the best and stockiest, and you are thus doing something to improve the strain.

Keep your soil busy all the time. Dr. Watts said, “Satan finds some mischief still, for idle hands to do,” and that might be paraphrased to read that “Nature has great store of weeds in idle lands to grow.” “Weeds are the farmer’s best friend, they force him to cultivate.” But that friendship is only true where it has that effect. The farmer who lets the weeds grow either in the garden rows or in the walks and hedges, is going to find them his worst enemy. They poison and suffocate his crop, and are also regular incubators of insects and diseases. The best way to fight them is to starve them out with paying crops. Therefore, as soon as one crop begins to ripen, plant another, and then another, and so on. To grow but one crop is risky, unless you are specializing and have prepared the best possible conditions for that one crop. For a special market this is very profitable. But usually companion-cropping is best. That gives two crops in the ground at the same time, one maturing before the other needs the space. Thus late celery may be planted between the rows of early celery; lettuce with early cabbage; radishes with beets or carrots; corn with squash, pumpkins or beans, and horse-radish with early onions or cauliflower.

Irrigation for arid soils and drainage for wet or clayey soils, are the two opposite methods which bring astounding results. Any sort of drainage is better than no drainage, but the best form so far discovered is the tile drain laid about two and a half to four feet below the surface. This carries away the surplus water and prevents the roots of the crops being suffocated. On the other hand, irrigation supplies to the dry lands the moisture they need. The tremendous irrigation works carried on by the Government in the sandy, hitherto barren, reaches of the west, are bringing results even more tremendous than the works.

Hard, wet soil will not grow crops and here is where the advantage of draining comes in. Drainage deepens the subsoil and removes the water; it deepens the surface also and makes more of the plant food in the soil available. Wet soil is sticky and hard for the seeds to push their way through; but drainage will improve its texture and make it crumble and fall apart easily, or as the experts say, it will make it “friable.” At the same time it will prevent it washing or “leaching” away. But even this does not tell all of the advantages of drainage. It warms the soil and by making the ground more porous allows the roots to go deeper in search of their food and moisture. This in turn enables plants to withstand drought and hot weather better and makes returns more sure. It also permits working the ground earlier in the spring and after rains, because, the more porous the soil, the quicker it absorbs and stores moisture that comes in rain.

There are germs in the soil which change the nitrogen into nitrates, the form in which nitrogen becomes the real plant food, and drainage favors the development of these germs. You see how important good drainage is.

Get the tools you need. You cannot afford to be without implements if you are cultivating intensively. That does not mean that you must get all the advertised garden tools, or even all that your neighbor has. Although a tool may be the best of its kind, that is not reason enough for buying it. You must have a use for it on your plot. Get whatever you have a use for, and get only the best. It pays in the long run.

A list of tools and costs is given in “Three Acres,” and in “A Little Land,” so it is necessary only to note here that the spading fork is a far better tool than the spade; some gardeners never use a spade. The spading-fork is easier to use and breaks the soil much

better.

The seeder, attached to the wheel-hoe, is also a saver of labor and of seed: it makes the rows quite straight, so that they are easy to keep free from weeds; it drops the seeds at even distances and if your soil is as fine as it should be, it covers them all just deep enough—provided you have learned to fix the gauges right to start on.

Combination tools, those that do several different things, sometimes work well, but they usually get out of repair quickly, and are apt to puzzle the beginner. Get the best and simplest form of the tool you want, and keep it always in condition for use. Tools that are not cleaned after use are spreaders of disease. Cleanliness prevents and cures. See to it that your cultivating tools, your harvesting baskets and bags, and your storage bins are thoroughly cleaned, and you will soon discourage the bugs. They will regard you as cold and unsympathetic, and your garden as a place to be avoided.

Don't be afraid to use manure, both stable and green, and when you must, use commercial fertilizer. But this is expensive and is only profitable under particular crops. You won't need it, if you keep the soil supplied with humus.

Don't waste kitchen slops or any other waste water. It all has fertilizing qualities that will help your garden. Even in the winter it is a good plan to pour your slops on the ground, choosing a different spot each day so that no one place may get too wet and leave surface pools. Mankind in the lump is stupid, so stupid that we drain our fertilizing matter into our harbors and then dig it out again at the cost of four dollars the yard.

But you need not be so stupid as that. Even some of our cities are now learning the value of sewage, notably San Antonio, Texas. This city, with its 85,000 inhabitants, has solved the problem of what to do with its sewage, although the city fathers leased the rights to a private corporation, instead of providing for the city's own disposal of it. This company carries the sewage six miles out of town, and has built five miles of canal, through which the surplus sewage not used in irrigating, flows upon a filter-bed where all solids are removed, and the water runs into a big basin which covers about 1000 acres. This basin being very shallow, the sun's rays reach the bottom of it, and purify the water, so that, though it enters one end of this basin as sewage, it flows out of the other as pure water. Chemical analyses and tests have proved this many times over, and we might take a hint from this at home to "raise our darkened windows and open wide our doors, to let the blessed sunshine in." It is the best destroyer of disease and impurity yet discovered.

The company's acres along the line of the canal profited so much from this irrigation, that farmers soon began to purchase the irrigating sewage water for use on their forage crop fields, and for root crops particularly. The solids are spread on the surface of the lands upon which the clear, purified water is to be used, and the results have been most satisfactory. San Antonio really makes a profit out of that which is costing other cities millions every year, and in doing this has shown us another way to work, in bringing into use all lands that are available in any way for intensive cultivation.

Plenty of manure and thorough cultivation are almost a complete protection against drought. If you have plowed deep, manured thoroughly, added humus and maintained tillage, you can laugh at the drought that would once have spelled ruin for the farmer in any part of the country. You have been told this before in this very book, but that is no reason why it should not be repeated. It is of such great importance, that the average farmer would make no mistake if he had it made into a motto printed in large and striking type, and hung it where he could see it a dozen times a day. It is part of the "How to Work," and a mighty big part, as you will learn, whether you practice it or neglect it.

Use your brains; that's what they are for. After you get your farm started, you can get cheap and unintelligent labor, to keep it going, if you wish; but you can only reap a profit from intelligent labor, and you must furnish the intelligence yourself. Plan your work, and make the most of your soil, your climate and your market. Things that everybody grows bring low prices, but things that you alone grow, or that you grow better than your neighbors, bring good returns all the year round.

We have to learn, you know, and if we won't learn by doing right and profiting by it, then we shall have to learn by doing wrong and suffering for it—"the way of transgressors is hard."

If you have very little time or very little land, you will probably get the best return for your time and money by growing radishes early in the season with lettuce, followed by bush-beans or tomatoes and then sweet corn.

Put some nasturtiums in any odd space and climbing nasturtiums and morning-glories on your fence, and you will have a very creditable looking garden—big returns for little expenditures.

If you haven't got any land, don't let that discourage you: grow some things in a window box and learn how, so that you have learned something when you do get some land.

You can grow mushrooms in half a barrel in the cellar. The thing to do is to get started growing something.

FOOTNOTES:

[4] NOTE.—Another way is to mix a little soil with rain water, stir it well, and put the litmus paper in it. Pure rain water is the only water that can be successfully used in this test.

Part II.

CHAPTER XIII.

ROOT CROPS.

Root crops are usually grown in drills and are not ordinarily transplanted. They are hardy and require little skill in the gardener, but they need a cool season and deep soil so as to grow long, firm and well shaped. The quicker they grow the better the quality, so that in the north it is necessary to warm the soil with stable manure and have it in good condition. Good tilth helps quick growth and therefore improves the quality; so that it rests with the gardener to make his root crops among the first and the best in the market. The price of a root crop depends almost entirely upon its looks, so have as few side roots as possible, and cut off those that may develop in spite of care. Forked or branched roots should not be mixed in when we market, for even a few such specimens lessen the price of all.

Early crops, such as radishes, beets, carrots and turnips, are sold in bunches of 6 to 12. All in the bunch should be of the same size and shape and tied neatly around the leaf-stalks with a cord. The leaves are left on these early vegetables, so they should be kept cool and moist, as wilted leaves also spoil the sale price. Beauty may be only "skin deep," but it commands the market.

Late root crops sell in bulk, and harvesting them is the hardest work connected with root crops. It is well to plow them out, cut off the tops, and allow the roots to lie in the sun only until the soil is dry enough to shake off. They are then ready for storing in pit or cellar, and are easy to keep.

RADISHES.

The radish is the earliest root crop, and the quickest growing. It is ready for market in three to six weeks after planting the seed; so it is a great financial help to one who is just starting a garden. It is a hardy crop requiring rather cool weather or shade. The radish responds well to hot-bed culture and the earliest spring varieties are usually grown that way. But even for planting in the open garden you need not wait long. Soaking the seeds will save several days. As soon as you can work the ground, even before all the frosts are over, radishes may be sown, provided there has been good preparation-tillage. To secure crisp, edible radishes, the growth must be continuous. Any interruption in development, or an overgrowth, makes the root stringy, bitter and often hollow. See that those in each of your bunches are even-sized and bright and clean, so that they will look like the delicacy that they are. A prime bunch of radishes is as pretty as a bouquet.

The radish is a partial season crop, and is, therefore, suited for all sorts of double-cropping. It is often sown shallow in the same drills with the other vegetables of later growth, because it matures so early that it breaks the earth crust for the slower seeds. Radishes may also be sown between rows of cabbages, beans, peas, etc., or broadcast in beds by themselves. One ounce of seed will sow about 100 feet of drill or eight to ten pounds to the acre.

Sow the seeds one-half inch deep (better sow too shallow than too deep) in rows 6 to 12 inches apart, if you have only a little plot; or in long rows a little farther apart if you use a wheel-hoe. Drop two or three seeds to the inch; this can be done only with a seeder attached to the wheel-hoe frame: later, thin out the seedlings to about two inches apart. Only large seeds should be used, the small ones being too slow maturing. They may be sown at regular intervals of seven to ten days all through the spring. It is usually difficult to grow good radishes in summer, unless you can select a cool spot and keep the soil cool, but some sorts of radishes do well in the hot weather. Although in America the radish is best known as an early spring crop, it may also be grown for winter use if planted in July or August, and stored like turnips or other root crops. The tops make good greens for boiling.

The radish is the easiest of crops to grow, and has only one serious enemy, the root maggot. This insect is one of the cabbage enemies also, and can be destroyed by injecting bisulphide of carbon in the soil, but that treatment is too expensive for the returns from radishes. The most effective way is to sow the radishes where the maggot has not been breeding, and thus starve the pest out.

The most popular varieties of radish are the French Breakfast, Olive-shaped, Scarlet Short-top, Chartier, Wood Early Frame, and White Box. Those that grow well in summer are White Naples, White Vienna, Strasburg and Stuttgart, while for use in winter Scarlet Chinese, Black Spanish and White Spanish are best.

BEETS.

Beets, like radishes, are a hardy crop requiring a loose, rich soil and continuous growth to reach their best and quickest development. They are easy to raise and respond readily to good tillage. The early or garden beet is usually a succession or companion crop, because it may be planted early and matures quickly. Although most kinds require two or three months for maturing, yet with some of the early varieties roots large enough for bunching may be had in six weeks to two months. The quickest sorts are the round or nearly round varieties, which may almost be called surface feeders. For this reason they require soil in excellent tilth and the richest, well-rotted barnyard manure. Indeed, the wise gardener will plow his land in the fall, and plow it deeply, too; then as soon as it can be worked in the spring run the cultivator and harrow over it, and plant the seed about 1½ inches deep in rows from 12 to 18 inches apart. The land must be kept well tilled and free from weeds, especially during the early part of the season. The long field-crop beet is now very little grown, as the early varieties may be sown late in the season for fall and winter use, and the Southern grown beets cost less in the late winter than it does to grow and store them. Even in feeding cattle, the beet has been largely superseded by the mangel, so that few are grown except the short round sorts for table use. The sugar beet is a field crop.

The seeds (which are really fruits, containing within a hard shell four or five seeds each) require a great deal of moisture to germinate. Some gardeners advocate throwing them into hot water and allowing them to soak for six or eight hours before planting. This makes them sprout more quickly. Beets come up in clumps and must be carefully thinned, until they stand 6 to 8 inches apart, although this is not done until the tops are sufficiently grown to sell for “greens.” In this way there is no waste, since top and root alike are used as a pot-herb. The contrast of the green leaves with clean roots attracts customers.

If you plant beets early in the season, say as soon as the ground can be worked, they may be followed by celery, late potatoes, cabbage or cauliflower; or they may be grown at the same time between the rows of some main season crop like cabbage. If planted in hot-beds or cold-frames it will not pay to transplant them, as they mature very early under such conditions, and may be bunched and sold without that labor. In July or August, and in some places even in September, the turnip-rooted variety may be sown for fall and early winter use, but special attention must be given to tilling them so that the soil may not be too dry. The best and firmest of the roots may be stored for winter use, and for better prices.

Early beets are sold in bunches of six, but late crops are sold in baskets or barrels. Five to eight pounds of seed are needed for each acre; one ounce will sow from 75 to 100 feet of drill. The average crop is from 300 to 400 bushels to the acre.

Beets have three serious diseases: root-rot, for which apply lime to the soil; leaf-spot, kept in check by spraying with Bordeaux mixture; scab, for which the only cure now used is not to plant where the land is infested.

Beets respond to special fertilizers, which may be used if the soil is already rich in plant food, and the market will afford enough profit to pay for the extra expense. At the New Jersey Experiment Station from 400 to 700 pounds of nitrate of soda well-worked into the soil before the plants were set out, increased the yield from 10 to 23 per cent.; and the earliness all the way from 17½ to 135 per cent. In the “Farmer’s Cyclopedia of Agriculture,” Messrs. Wilcox and Smith of the Department of Agriculture, say that “where earliness is of primary importance, nitrate of soda can be used with profit with this crop even on the richest of soils.”

If you can’t get your root crops early, get them late. When the mercury goes away down, the prices go away up.

CARROTS.

Besides being a hardy crop that may be planted in the early spring as soon as the ground can be worked, carrots have the advantage of having no serious insects or diseases. They require a clean, mellow soil, that will not “bake” over the seeds, and the best of surface tillage. Carrot seeds are so small and so slow in sprouting, that it is good practice to plant radishes or turnips or

other quick seeds in the same row, to help break the crust for the tender seedlings. The young carrots have such a slight hold upon the soil, that they need petting, only the shallowest, surface tillage being possible, yet scarcely any of the garden crops need tillage more. But once let the carrots get established in the soil, and they are easy to grow and give good returns. They are sown thickly about one inch deep in rows from 12 to 18 inches apart. When they are well up, they should be carefully thinned so as to stand two to three inches apart in the row. The early varieties will bear forcing and respond to hot-bed culture, but they are slower of growth than radishes or beets, requiring from two to two and a half months to be ready for market. They are tied in bunches of six with the tops left on, and are in great demand in the early season when small and bright and tender.

Carrots are of two main types, the early, small variety and the large sort grown in the field for winter use. The large kind is not much grown, because the smaller varieties may be planted late for winter use, and as feed for stock, carrots are no better than the larger root crops. If you grow the early variety for winter use, you will need to be sure that the soil is in good tilth, as dry or weedy soil would be fatal to carrots. Maybe you are tired of reading that all these crops need good tillage; but you will be much more tired if you neglect it. This crop may be sown as late as the middle of June in the Northern States, and the ground should be sown with some early crop, like radishes, to keep it in good condition until needed for the late carrots.

Carrot seed is sown thickly, about two pounds of seed being required for an acre, or one ounce to about 300 feet of drilled row, if the seed is fresh. A good crop of carrots is from 200 to 300 bushels per acre.

The best varieties are the Early Forcing, which may be grown in hot-beds, cold-frames, open garden in the spring, and also in the fall for home use; the half-long Danvers for a good, reliable mid-season crop and the Long Scarlet for a good late crop.

These root crops are among the prettiest “fancy goods”—where they can be sold directly to well-to-do people they bring fancy prices.

TURNIPS.

The turnip is such an easy crop to grow that the gardener would have a snap with it if it were not for the snap that the root maggot has. It is a hardy, quick-growing crop, requiring a cool, short season and a moist soil. The turnip is so hardy that the herbage can bear considerable cold without real injury, so that when grown for winter use it is left standing in the field until the black frosts; but the roots will not stand such hard freezing as parsnips or salsify.

Turnips should be planted in moist, rich soil to insure quick sprouting, because their chief value as food is the result of rapid growth. Like the radish, the turnip, if it grows slowly, is likely to be tough, woody and stringy. True turnip has soft, white flesh (sometimes the boys eat it raw) and the roots are flatly rounded, while the leaves are rough and hairy. The seed is sown as soon as the soil can be got ready in the spring for the early crop, and as late as the last week in July in the Northern States, or the middle of August in the Middle States, for a fall crop. They are ready for the table in six to ten weeks. Turnips are planted from 1 to 1½ inches deep in drills from 10 to 18 inches apart; one ounce of seed for every 200 to 300 feet, or one pound to the acre. Plants should be thinned until they stand three or four inches apart, and later, as the roots are pulled, a foot of space will allow of full development.

Turnips suffer so from root maggot, that where the land has become infested with this pest, it is better not to try to grow them until the insects are starved out, because the only effective treatment that we have found so far is to inject bisulphide of carbon into the soil, which costs too much for turnip crops.

PARSNIPS.

Unless your preparation-tillage has been thorough, there will be no good parsnips for you. They require cool, very deep soil in excellent tilth to make good roots a foot long, straight, clean and tapering. A lumpy or shallow soil makes the roots branchy, and of little market value. Parsnips are usually sown in drills, far enough apart to let the wheel-hoe in; sow thickly and then thin out the rows, leaving plants about six to eight inches apart. We have to sow thickly because some seeds may be bad, for parsnip seed does not retain its life for more than two seasons. An ounce of fresh seed will do for 200 to 250 feet of drill, or about four pounds to six pounds to the acre.

The seeds sprout so slowly that it is well to plant some quick-growing seed with them to break the soil, else it may have to be broken by hand. The parsnip is hardy and the seeds may be sown as soon as the ground can be put in condition, but it must be the main crop, for it takes the whole season to grow the long roots. The roots may be left in the ground until the next spring, as the hard winter freezes do not injure them. In that case you must store a large part of the crop in cool pits or cellars, because the best price

is obtained in the late winter or very early spring when the ground is often frozen so hard that you can't pull the roots up. It would not pay to blast them out, you know. There need be no waste where stock is kept, because the ragged roots make excellent feed. The Hollow Crown and the Student varieties are the standards. A good crop is 500 to 600 bushels to the acre, but under good conditions, this can be bettered. No serious pests or diseases consume the parsnips, so men and stock get all that grow.

SALSIFY.

The salsify plant tastes so like an oyster that it is called the oyster plant. It is grown for kitchen use only, not for stock. Like its cousin, the parsnip, it must be sown in deep, rich soil and given the whole season to mature. Salsify can be left in the ground all winter, unless it is needed for the late winter or early spring market. The seeds sprout quickly and may be sown as early as the soil is ready. Like beet seed, the salsify seed is really a fruit, long and hard like a stick, and it is somewhat difficult to use a seed drill in sowing them. An ounce of seed sows only about 70 feet of drill; an acre requires eight to ten pounds and a good yield is from 200 to 300 bushels per acre. There are no serious insects or diseases.

There are two important modifications of salsify known as Black Salsify and Spanish Salsify. The regular type is a biennial, though cultivated as an annual, becoming wild and losing its fleshy root if left in the ground longer; but the Black, which is grown just the same as the main type, is perennial, and the roots continue to enlarge, yet to remain edible, though left in the ground more than one year. It has broader leaves than the regular salsify and a long black root, yellow flowers and light seeds.

Spanish salsify is not generally known in this country. Its root is much lighter in color and not so strong in flavor, but with careful cooking it develops other qualities of its own that are most agreeable. Moreover, it is easily cultivated and yields larger returns than the regular salsify and the average person would not know the difference. It is sown and cultivated just as salsify is, and when bleached the young leaves are eaten like cardoons, that is, as a pot-herb.

HORSE-RADISH.

Although horse-radish is a perennial, it gets woody the second year, so that the market gardeners grow it from fresh cuttings, called "Sets," every year. These cuttings are taken off the side roots, from three to seven inches long, and from the thickness of a lead-pencil to that of a little finger. The cuttings are made when the roots are dug in the fall and may be stored all winter. Horse-radish grows very easily, but as it is a late season crop, and needs cool soil, there is nothing gained by planting it early. It requires very deep soil if the roots are to grow straight, long and tender. Only long, large, even shaped and uniform roots bring any price in the market. It may be planted with early cabbage or beets, and when they are harvested, the horse-radish takes the land. It will grow until freezing weather and is the better for being left in the ground as late as possible. Sets are planted either upright or slanting, three to five inches below the surface and from twelve to eighteen inches apart in rows. If they grow too fast they may be cut down two or three times, as horse-radish stands considerable ill-usage, if it is planted deep and in good soil. Before sending to market, wash the roots and trim them of all side shoots; tie them in bunches of six or eight; or they may be sold in bulk or by the barrel. The price ranges from ten to fifty dollars a ton, and in good rich soil four tons can be raised to the acre. The usual yield is only two tons. The extra two come from knowing how.

But horse-radish can easily become a bad weed, for weeds are only plants misplaced. So plow the roots out as soon as you have dug your crop and have them removed. Although it is next to impossible to get them all out, they cannot do much harm if the ground is kept thoroughly busy with some other crop. There is a good deal of the Old Nick in Nature, and wherever she finds idle land she sets to work to grow weeds. She would just as readily help your crops; so it is for you to profit by her willingness.

CHAPTER XIV.

TUBER CROPS.

POTATOES.

A heavy yield of potatoes may be simply a matter of moisture and frequent tillage. The potato likes Scotland[5] and Nova Scotia because it thrives best in deep, cool, moist soil, finely pulverized and containing much potash. Knowing the conditions under which any crop grows well, is equivalent to growing a big crop, to the careful farmer, so if you want some potatoes, you may as well get the most possible. The average farmer raises 75 bushels to the acre, but it pays to be above the average. You ought to be ashamed to grow less than 200 or 300 bushels even taking 75 as a starting point, for, when you consider that by the exercise of

brains and labor, all the way from 600 to 1300 bushels per acre have been produced, you may well decide to prove what you can do. You have a chance to beat the record.

Potatoes should be planted deep and early. If they are planted too near the surface they will ripen before they are fully grown or maybe get sunburned and unfit for eating. Choose your best potatoes for seed, if you plant from your own crop; or buy only the best varieties, if you must buy. But it is well to remember that there is always danger in potato seed raised elsewhere than on your own patch where you can watch conditions. Don't use a potato for seed if it has a black thread running through it; a roughened or irregular circle on the skin, or a hollow center. Burn all such; else you will have diseased crops and give yourself no end of trouble and expense. Plant the seeds at least four inches deep and plow them in. The surface should be harrowed two or three times before the plants come up, and the crop should have light, surface tillings five to eight other times during the season.

Potatoes are planted in "drills" or continuous furrows, 27 to 42 inches apart, at intervals of 9 to 18 inches, and it requires from 8 to 18 bushels of potatoes to plant an acre. Most farmers plant too sparingly. There has been much book discussion as to the size of seed cuttings, but the most economical size is one weighing about three ounces or the size of a large hen's egg, with at least one good eye. The potato cutting is food; therefore the larger the cutting the more food, and the more food the better early growth, and the better the early growth the better the yield. Bailey claims that a piece containing too many eyes means too many sprouts contending for that food and each weakening the other in the struggle for its own existence.

For early potatoes, the only ones that can pay in a small plot, remember five different things: (1) good site and an early soil; (2) land prepared either by special plowing the fall before, or by growing late-tilled crops, that the soil may be in good tilth; (3) free use of concentrated, quick-acting fertilizers; (4) early varieties of potatoes; (5) sprouting the sets, so that the short, thick, firm, colored shoots are secured. To secure these, light and a moderate degree of warmth, 40°-50°, is needed. Nothing pays better than sprouting.

No crop needs spraying more. Unless it is frequently sprayed, it is almost certain to be attacked by the potato bug, the flea-beetle and blight, and the yield cut down. Dry Paris green puffed on while the leaves are damp with dew, ends the troubles of the bug, and Bordeaux mixture can be sprayed for blight. No specific has yet been discovered for the flea-beetle, but it does far less damage where Bordeaux mixture is freely used. I have heard of letting the chickens loose on the flea-beetles.

SWEET POTATOES.

The common or Irish potato does badly in the South, except as an early crop, because the climate is too warm, but where the common potato suffers, the sweet potato thrives. It requires a warm, sunny climate, a long season, and warm, loose soil, with plenty of moisture during growing time, and less during ripening. It is very tender and cannot stand frost. It is grown extensively as far north as the sandy lands of New Jersey.

The soil must be rich, loose, and well drained and liberally fertilized with well-rotted manure. Wood ashes will help the growth of the tuber most satisfactorily.

Only one variety of sweet potato, the Spanish, is cut and planted like the common potato. All other varieties are grown from "slips," or, as they are sometimes called, "draws." A whole potato is laid on a hot-bed and covered with a couple of inches of loose soil or leaf-mould. Very soon it begins to sprout and when the shoots are from three to five inches high, they are broken off next the tuber, and planted. Their roots have already begun to form and these are the "slips." The same potato or tuber, will give another set of slips if allowed to remain in the ground. In the extreme south no hot-bed is necessary to start the sprouting.

Another method of obtaining slips is from cuttings from the ends of the vines. Take cuttings from 10 to 12 inches long, from the earliest planted or the most vigorous vines. Having removed all the leaves except those at the very tip, plant the cutting lying down with only an inch or two of the tip showing. The rows should be about three feet apart and the slips in the row 18 inches apart. The average yield is from 200 to 400 bushels per acre.

Sweet potatoes suffer from several fungous diseases which are discussed in New Jersey Experiment Station bulletins on Sweet Potato Culture. Leaf blight may be checked by the use of Bordeaux mixture, but rotation is the cure for tuber crop diseases.

FOOTNOTES:

[5] Ireland is not really the land of the "praties"; the average yield of Great Britain is higher than of Ireland.

CHAPTER XV.

BULB CROPS.

All bulb crops are hardy, liking cool seasons and moist rich soil with a loose top. As a rule they are seed-bed crops, but are sown early in the open field. They grow from seeds or bulbs and may be raised as main or secondary crops and treated like onions. Their tops are often used for seasoning.

LEEKS.

To the average American, there is but one important bulb crop, the onion, but the foreign-born use garlic, leek and others also. Of these the leek is the mildest flavored and the best worth knowing. It is grown from seed sown in the early spring, and requires the whole season to reach full development. It produces soft bulbs and thick leaves, both being used for seasoning. The leek is stored green, as celery is, being set in earth in a pit or cellar.

GARLIC.

The garlic is the strongest of all the bulb family in flavor. It is grown from “cloves,” as the separate sections of the bulb are called, and is planted early. It does not fully mature until the end of the summer or early fall.

SHALLOT.

Shallot is much like garlic, only it is milder, and is grown in the same way. There is one interesting difference, however, between the two. The “cloves” of the garlic are all encased in one outer skin, those of the shallot grow separately.

CIBOULE AND CIVES.

The Ciboule or Welsh onion, and Cives, are grown for their leaves which are used for seasoning. The Ciboule is the most like the common onion and grows the same way and requires the same cultivation. Cives grow in dense tufts and are propagated by separating the tufts and planting a section. They are perennial, and make a good border for the garden walk, combining grace and toothsomeness.

ONIONS.

It pays to grow onions intelligently. They take lots of care, but they repay the time and trouble.

You cannot get the best results from onions by beginning now, at the moment you start your garden, to sow your seed. Onions require that you should begin last year, so to speak. The ground should be well plowed in the fall, after having been in use with good tillage all the previous season, and the surface soil must be in super-excellent condition. The onion is practically a surface feeder, and as the seed sprouts slowly, and the baby plants are delicate and slender-rooted, conditions must be absolutely right for a good growth. In fact, no other vegetable crop, grown on a large scale, requires such fine surface soil. Hard or baked soil is sure to give a poor crop. The surface must be kept loose and in good tilth, and low, level land is the best place for your onion patch.

When the ground has been plowed, go over it carefully and break up all the clods or lumps, and remove all stones and weeds. Do not use coarse, fresh stable manures, as that leaves the ground too coarse in texture, and moreover increases the probability of weeds, and weeds are death to onions. Only fine, old, well-rotted stable manure may be used, and this must not be plowed under, as it is the surface soil which must be rich. Commercial fertilizers, especially the sorts rich in potash, are of great value in growing onions, and, because of their potash, wood ashes make an excellent top dressing for the onion patch. Keep the soil finely pulverized and you will then have ideal conditions for planting your crop. Next get good seed. Good onions often give poor seed, but cheap seed always means poor onions, so buy the best seed always.

Reclaimed marshes, freed from roots and peat, and thoroughly fertilized, are ideal places for growing onions. The rows or drills, which must be 14 inches apart, must also be perfectly straight, else the necessary cultivation cannot be given. The crop often needs two weedings by hand when the plants are very young, and frequent cultivation by the wheel-hoe. Now the wheel-hoe cannot do good work on rough or uneven ground, and its best work is none too good for onions, so you see where you are at.

The onion crop is divided into two classes, the early crop and the main season crop. Early crop onions are immature, green, and are tied in bunches for market; main season crops are dry and are a staple product.

Early onions may be grown from seed, but are usually grown from bulbs. There are three kinds of bulbs for planting: “top” onions, potato or “multiplier” onions and “sets”; the first two are distinct types, but “sets” are only partly grown onions. “Top” onions are really small bulbs which grow on the top of the plant instead of fruit; “multipliers” are onions with several hearts or cores, each of which may be planted and will give rise to another bulb, which, in its turn, will develop two or three more cores. The process is continued indefinitely.

“Top” onions start quickly and soon give edible onions. If the bulb is planted out the following year it will send up a stalk and produce a new crop of tops.

To raise “sets,” seeds are sown thickly on dry, light ground, where they soon crowd each other, and by midsummer anyway, the tops die for lack of room, food and moisture. The bulbs, which should then be from one-half to three-quarters inch in diameter, are picked, cured and stored as ordinary onions are. When planted in the spring they start to grow again and soon produce eatable bulbs.

The new early onion culture is growing onions from seedlings raised in the hot-bed or forcing house, and transplanted as soon as the weather permits. By this method the large, quick-growing Southern varieties, Gibraltar and Prize-taker, come to perfection in the North. Our season is too short for this by the ordinary open planting. This “New Onion Culture,” which is not so new, after all, except in the middle East, is fully described by T. Greiner, in his book published by the Orange Judd Company, N. Y.

In the main season crop, earliness is not so necessary, and less fertilizer will do, so long as it is the right kind. Seed is sown as early as possible, as the onion likes a cool season. In the garden, it is sown thickly because the onion often fails to sprout, but in the field, it is sown more carefully, waste of seed and the thinning in the big field being expensive.

On some land the onion runs to tops, particularly where there is too much moisture, or the ground is too new, or coarse manures have been used. If the tops are still rank and green in late August or early September, it is a good thing to break them by rolling a barrel over the rows, that the growth may go to the bulbs.

The trouble with onions does not end with growing them. They are a difficult crop to handle and store, unless the fall is warm. After they are pulled they must dry a day or two, either in the field or under cover—cover is more expensive but the bulbs have a better, brighter color. The bulbs must be free from dirt and the tops cut off about a half-inch above the bulb, neither more nor less, else the bulb will suffer in marketable value. It must be a clean cut without ragged ends, and the outer skin or covering must not be broken. If the crop is uneven in size, as is quite apt to be the case, sort them over, because one misshapen or under-sized onion in a dozen, will materially lessen the price received for the crop. There are so many good vegetables on the market today, that the consumer is growing finicky, and wants only the best looking as well as the best tasting. Be careful to give him what he wants, and he will give you what you want—good prices—in return. The sorter may be a very simple contrivance, consisting of a rack or trough with a slat bottom through which small onions will drop. When raised to a convenient height on a slant it is easy to work the bigger onions over the end of the rack into boxes or baskets below.

Most farmers prefer to sell their onion crop in the fall, because it is difficult to house it. Mature onions will not stand freezing, unless they can be kept frozen all winter and allowed to thaw gradually in the spring. But this is a risky process and often results in heavy loss. They need a steady warm temperature, and many store houses are heated to ensure safety from frost.

It takes an ounce of onion seed for 150 feet of drill, or from 3½ to 5 pounds to the acre. A good crop for an average farmer is from 300 to 400 bushels per acre, but an average crop for a good farmer is 600 to 800 bushels per acre; and some have grown as high as 1100 bushels to the acre. You can choose your own class.

The root maggot is the worst enemy the onion has, and there is no really successful method of fighting it. Infested land should be used for other crops that the root maggot will not feed upon, until he is starved out. Rust and smut which also affect onions, may be practically cut out, or at least held in check, by the use of Bordeaux mixture, but rotation is the best remedy for smut.

CHAPTER XVI.

COLE CROPS.

Cole crops are among the hardy plants of the garden and field, requiring plenty of moisture at the roots, a cool season and cool soil. Hence their name, Cole meaning cool. They are mostly seed-bed crops and need considerable space in which to spread. They are grown for their tops, rather than for their roots or fruits.

CABBAGE.

Cabbage culture needs a cool deep soil that will hold moisture, and continuous growth from start to finish. Its other essentials are: extra care in the selection of the seed; frequent and thorough surface tillage; avoiding the root maggot, club-root, and rot, by proper rotation of crops, and by destroying the cabbage worm as soon as it appears. “A cabbage head” may mean a stupid man, for “a cabbage head” can’t take care of cabbages.

The demand for cabbage has increased more rapidly during the past ten years than for any other vegetable in the market. For sauer kraut alone the demand is enormous. Where a few hundred barrels would supply all the demand twenty years ago, tens of thousands of barrels are now needed annually. Its use was at one time largely confined to the German in this country, but that is no longer true. So there is always a market for cabbage, and if you are willing to take the pains necessary to grow good cabbage, you will find it a paying crop. Cabbage is also largely grown for stock-feeding, and all the animals, from the horses to the fowls, are glad to get it.

There are, of course, the two sorts of crops now so usual in market-gardening, the early and the main season crops. The early crop is started under glass either in the hot-bed or forcing house, while the main season crop is sown in seed-beds or in the open.

The best soil preparation begins the fall before, with deep plowing and from 10 to 20 tons of manure to the acre. Then, if the land is at all acid or has not recently been limed, it is well to apply lime at the rate of 1000 pounds to the acre, and plow that in along with 50 pounds of nitrate of soda. This will supply the food for the cabbage, which is a gross feeder, and won’t thrive without plenty of food. Farmers who raise it in large quantities, give it three applications of nitrate of soda after it is quite well grown. They use about 50 pounds to the acre each time, about ten days apart.

If sown in hot-beds, care must be taken to harden the cabbage sprouts by gradual exposure to the air before transplanting, so as not to cause any serious delay in growth. In field-grown cabbage, likely to be used in part at least for stock feeding, the plants should stand from 24 to 30 inches apart, in rows not less than 30 inches apart. This gives room for the heads to increase in size and weight. Under these conditions an acre will produce from 7500 to 9000 plants. But on small areas, where the crop is intended for market, the plants may be crowded somewhat, to keep down the size and to secure an average weight of four to six pounds each. In this way an acre will bear 10,000 plants. Cabbage should be cultivated once in a week or ten days until the heads touch in the rows. If your cabbage is uniform in size, has few outside leaves, very little stump or core when cut open, closely packed leaves lapping in the centre, freedom from disease or insect injury, and is true to name and type, you should secure the uniform price of five cents a head in good markets.

Cabbage suffers from many diseases and insects, and the gardener needs to be on the watch constantly if he is not to lose his crop after all his labor. The cabbage worm makes its appearance early, and should be destroyed at once; while for club-root, black rot, etc., rotation is our only usual remedy.[6]

Different varieties thrive better in different localities. You must experiment in a small way, or find out what your neighbors have done, keeping a record of the sort that does best under your conditions, and then plant only that. Near New York City the Bergen Drumhead does wonderfully well, but in some western parts of the country it has less success. The Newark Flat Dutch, on the other hand, for an early cabbage, does well both east and west. For a late season variety the Premium Flat Dutch is excellent.

To show the possibilities of profit in cabbage, Professor Bailey, in his “Vegetable Gardening,” quotes from an expert cabbage grower in Green Bay, Wis., as follows:—Assume that you have first-class land worth $200 per acre:

Interest and taxes per year will cost, say $15.00 Forty loads manure at $1.00 per load. 40.00 Plowing and fitting the ground 3.00 10,000 plants at $4.00 per thousand 40.00 Setting and watering 5.00 After-cultivation 10.00 Harvesting and marketing 50.00 -------- Total $163.00 8000 heads sold at $3.50 per hundred 280.00 -------- Net profit $117.00

If you get only 8000 plants out of 10,000 set, it is a little below the average return, and as the market price is estimated at only 3½ cents per head, there is no trace of exaggeration in these figures. The estimate was made ten years ago.

A crop of cabbages can be grown and harvested in 100 to 110 days, which makes possible two crops from the same piece of ground in the one season. There are two ways of planting the first crop. One is to use a good rich seed-bed and sow the seed in November, the favorite variety being the Jersey Wakefield. When the plants are three or four inches high, transplant them to cold-frames in a protected spot and let them winter there. In the spring they will soon start growing and be ready for transplanting to the field early. The only drawback to this method is, that the plants being really old when spring comes, you are apt to lose a good many by their running to seed. For this reason, another method is rather to be preferred. Use the same variety of seed, but sow in hot-beds in February, and as soon as the plants are three or four inches high, transplant to cold-frames. If they are not too crowded, they will be ready for planting in rows in the field by April 1. But you must remember that the cabbage is a heavy feeder and that your soil must be rich and full of humus.

One noted cabbage grower in New Jersey says he plants his cabbage with a potato planter, which makes the rows 3 feet apart, distributes the fertilizer, and makes the ridges for the plants all at one time. He levels down the ridges with a plank drag which covers two rows at a time. The fertilizer is of high grade, applied at the rate of 1000 pounds to the acre. If plants are set 20 inches apart, it will require 10,000 for an acre. He cultivates thoroughly until the cabbages begin to head; then while cultivating once more, he applies nitrate of soda at the rate of 150 pounds to the acre, putting it on the row close to the plants, but not on the plants. This makes the cabbage head up quickly and uniformly, and makes the heads crisp and tender, besides increasing the yield enormously. This crop should all be marketed by July 4, and the yield should be from 8000 to 9000 heads per acre.

For the second crop, sow the seed in a good bed in the open, about the last of May and by July 15 at latest, the plants can be transplanted to the field. Between marketing the first crop and transplanting the second, the ground should be again thoroughly prepared by the addition of 1000 pounds of fertilizer to the acre and 150 pounds of nitrate of soda. Plant the same as in first crop. The variety most used is the large, early Dwarf Flat Dutch.

In growing late cabbage there is much more danger of maggots and other insects destroying your crop. The New York Experiment Station has tried a simple device which has given satisfaction so far as tested. This consists of screening the bed completely with cheesecloth which protected the plants from maggots. From 1800 square feet of screened bed 50,000 plants were transplanted to the field, while from an unscreened check plat intended to plant 40 acres, only enough plants for four acres were secured. The plants were “hardened” by removing the screen one week before transplanting. There was no more wilting than with plants grown in the open. This is cheaper than any form of insecticides.

KALE.

Kale requires much less care than cabbage, and is usually sown where it stands. It is probably nearer the original type of cole plant than any other, and even in cultivation produces no heads, but very large, heavy foliage. It is a very hardy plant, and is grown especially for spring and fall crops, and is much used as greens at seasons when other greens are not to be had. In the Northern States the seeds are sown in the spring and the plants are ready for use in the fall. When the crop has been thinned, the plants that are to reach maturity should be from 10 to 20 inches apart, and the distance between rows may depend upon the sort of cultivation to be given. In large areas of kale, horse-cultivation is best, but in a small plot the usual 12 to 18 inches will allow of wheel-hoe work.

Kale is such a hardy plant that frost will not hurt it, and the crop is often allowed to stand in the field until very late in the season, or even all winter. The large outer leaves are improved by frost. In the South and Middle South, kale seed is sown in the late summer and the young plants allowed to stand in the field unprotected all winter, but this cannot be done in the North. There the young plants need cold-frame protection. For this reason there is little winter-grown kale in the North, and the extensive supply that comes from Virginia from January until late spring makes it unprofitable to force it for early spring in the North.

There is a form of kale called collards, which is much grown in the South, especially where the climate is too hot for successful cabbage-growing. The seed is sown very early in the spring in protected seed-beds, so that the crop may get its growth before the hot weather sets in. It is much like cabbage, and sometimes young cabbage plants are raised for greens, and are called collards. Kale is subject to the same enemies as cabbage (which see), and requires the same sort of cultivation.

BRUSSELS SPROUTS.

Brussels sprouts are closer kin to kale than to cabbage, although not exactly like either. All cole crops have similar needs in soil, food and tillage, so what holds for one may be taken as true for all, except that kale and Brussels Sprouts do not exact so much

care as the others. In the Northern States, the seeds are generally sown quite late in the season that the crop may not come to perfection too early, as the plants are most prized in late autumn and early winter. A large part of the crop's growth is made in the cool weather of early fall. If the seed is sown in seed-beds in June, the plants will be ready to set out late in July or early in August. Where the winters are mild the crop is often left in the field until used, but in the North it is usually dug and placed in pits, like leek or celery.

The stalk of the Brussels sprouts may be from two to three feet high, although where the season is short, the dwarf or half-dwarf varieties give surer crops. All along this stalk, from the root to the crown of leaves at the top, grow tiny baby cabbages, each of which is called a "sprout," and averaging from an inch to two inches in diameter. When the sprouts are small and tender they are the most delicately flavored of any of the cabbage family. In many places, however, the demand is very limited.

Success in raising a good crop depends chiefly upon careful selection of seed. There is no crop which runs down so quickly, and in which greater care is necessary in choosing only the best for seed. It is subject to the same diseases as other cole crops.

CAULIFLOWER.

The cauliflower is more particular than cabbage, both as to climate and cultivation. It won't head up in the heat and must have a cool, moist climate to reach perfection. It also needs a constant water supply and therefore demands the best of tillage. It will grow only from the best of seed, and as it is easily sunburned, it is grown chiefly for early and late crops. For early crops the seeds are sown in hot-beds or forcing houses, and transplanted as soon as the weather is settled, so that the crop is off in late June or early July. The best varieties for this early cropping are the Snowball and Paris, variations of the Early Dwarf Erfurt. The fall crop is started in seed-beds in the summer and transplanted to the garden. For this crop some of the larger and later growing varieties may be planted.

Cauliflower is grown to best advantage along the northern sea-coast States, Long Island, the shores of the Great Lakes, and in the Puget Sound region, and wherever irrigation is practiced. Where the climate is at all inclined to be sunny it is well to tie leaves over the young heads to blanch them, otherwise they will brown in the strong light and bring a lower market price. It is necessary, too, to save all the moisture there is in the soil by the most careful tillage. Tillage should be shallow but frequent all through the growing period. "Buttoning" or the throwing up of irregular growths which spoil the evenness of the head, comes from poor seed, or dry soil, or too great heat; and also from allowing the plants to be checked in their growth and then started again by renewed cultivation. The crop requires steady and persistent care, rather than occasional energetic care, and will repay you for all your effort.

The best cauliflower seed—and that is the only sort worth using—is expensive, often running as high as $3 to $5 an ounce, and you may be tempted to choose the cheaper sorts. But the best seed is of vital importance in growing cauliflower, the cheaper kind being given to "buttoning," which lessens the price you can get in the market. The best seed in the market has so far come from Denmark, but the Puget Sound growers are beginning to rival the Danes. There is a family of long-season, late-growing cauliflowers, called broccoli, but they are little known in this country. Things that are little known are all right to eat and to show, but they are usually hard to sell.

KOHLRABI.

Although of the cabbage family, kohlrabi looks and tastes more like turnips and is cultivated like turnips. It is grown for the thickened stem or tuber which grows above the ground, and if eaten when young is very tender and more delicate in flavor for early spring use than turnips. It is also excellent for stock feed and is grown extensively for that. The best variety for garden use is the White Vienna, and the tubers should be eaten when from two to three inches in diameter. Like all cole crops they need continuous growth, otherwise they become bitter and stringy. Successive sowings of the crop may be made and when thinned the plants should stand from six to ten inches apart. They require from two and one-half to three months to mature and may be planted and tilled just as turnips are.

Cole crops all suffer from the same insects and diseases and it is well to get the latest advice upon how to deal with them. For root maggot, a most troublesome pest, read Cornell Bulletin 78 (published at Ithaca, New York), though the only really effective remedy is well-planned rotation. In this bulletin, Slingerland recommends placing tarred paper cards close to the young plants to protect them against the maggot; rubbing the eggs of the maggot off the base of the young plants, and injecting bisulphide of carbon or carbolic acid emulsion into the soil about the plants. It is necessary to use a syringe made specially for this purpose.

The Cornell Bulletin 104, deals with cut-worms, and New York Bulletins 83 (p. 657) and No. 144, tell about the cabbage worm or butterfly, the common yellow butterfly. Better look them up. They recommend persistent use of Paris green on the first crop, and a mixture made of five pounds pulverized resin; one pound concentrated lye; one pint fish oil or any cheap oil except tallow; five gallons water. The same treatment does for the cabbage looper.

For aphids, or lice, read the New York Bulletin 83 (p. 657) and Florida Bulletin 34 (p. 270). The injection of bisulphide of carbon in the ground, or the application of kerosene emulsion to both sides of leaves when young and small; tobacco; pyrethrum; Persian insect powder—any of these will prove more or less effective.

New York Bulletin 83 (p. 683) will tell you about methods of dealing with the Harlequin Cabbage Bug. Hand-picking is effective, and with clean culture, should eradicate this pest.

Club-root is really cured only by a thoroughly planned system of rotation, although air-slaked stone lime, applied in the proportion of 75 bushels to the acre, does good work. Read New Jersey Bulletin 98.

FOOTNOTES:

[6] NOTE.—Some experts think that lime is the one great soil doctor, especially in a garden where crops are plowed under, lots of manure is used and there is not much chance for crop rotation. Heavy doses of lime will destroy many fungous diseases and also kill off a good many insects, especially the soft-skinned kind which gather as crops are grown in the same place year after year. It would scarcely be possible to grow good cabbage in the same spot for a series of years without heavily liming the soil. It prevents club-root.

CHAPTER XVII.

POT-HERB CROPS.

Pot-herb crops are “greens,” grown for their leaves. Unless the growth be quick and continuous, the leaves will not be crisp and tender. Quick and continuous growth can be secured only by having the soil in good condition and giving the crop careful tillage. Furthermore, greens are mostly surface feeders, so that the surface soil must be in excellent tilth, and contain much plant food. They demand cool weather and are usually grown as succession- or companion-crops, because they do not require the whole season to mature.

SPINACH.

Spinach is a spring crop and a fall crop, because spring and fall give the cool, moist temperature it needs to come to perfection. Spinach belongs to the pigweed family and is a cousin to the beet. There are two varieties, the prickly seeded and the round seeded. The prickly seeded is the hardiest, and is most commonly used for fall sowing.

Farmers in the North used to grow spinach extensively under glass, but of late years the large out-door crops grown around Norfolk, Va., have spoiled the profit in that, and the Southern product takes its place. The spinach for early spring is sown in the field or garden in September and should be thoroughly established before winter, with a spread of leaves at least three or four inches.

As far north as New York State it is left out uncovered all winter and does not suffer unless the frost causes the ground to “heave.” If straw or litter can be had without trouble or expense, the spinach can be covered lightly as that often prevents “heaving.” If all goes well, the plants resume growth early in the spring, and may even continue growing during the winter if the season is mild. It is ready for market in April or May and should be off the ground in June to make room for the main crop. Southern spinach is marketed from late November until April or May.

Although spinach is a comparatively easy crop to grow, it needs certain conditions for perfection. The land must be rich and well drained, and liquid fertilizer must be applied after the crop gets started. Some put manure on the plot in the fall, and, as it leaches during the winter, it fertilizes the plants and starts them growing in the spring. Hen manure may be used. But the best way is to apply nitrate of soda or sulphate of ammonia in a weak solution so that 50 to 75 pounds will be sufficient for an acre. This is generally used in a sprinkler and is applied two or three times at intervals of a week or ten days, using each time, 50 to 75 pounds of fertilizer.

Spinach is sometimes sown in the spring in the place where it is to grow. But in that case, the position chosen must be a warm one, and even then, although a better stand is often obtained, the crop does not mature quickly. It is still occasionally started under glass and transplanted to the garden, and sometimes it is grown in frames all the way through to maturity. Gardeners who want to hasten their crop frequently cover it with glass during February and March, and it responds well to this treatment.

A variety known as New Zealand spinach, which is hardly a true spinach, thrives in summer, but as greens are not greatly in demand in summer, it has not become very popular in this country.

An ounce of spinach seed will sow 150 feet of drill, or 10 to 12 pounds to the acre. It is so necessary to have excellent drainage for spinach, that the land is usually plowed into low ridges or beds six to nine feet wide. The spinach is sown lengthwise of the beds 12 to 18 inches apart, according to the sort of tillage to be used.

CHARD.

One of the best of the pot-herbs, though not so generally known, is the chard or leaf-beet, which usually requires the whole season to mature, although it will give a succession of leaves from early summer until fall. The leaf-blades and midribs of the chard are very broad, and are usually white or slightly tinted, instead of green. Gardeners often blanch them further by tying the leaves together while growing. The seeds are sown in the spring as thickly as the ordinary beet is sown, and the plants are thinned until they stand six to twelve inches apart in the row.

MUSTARD.

Mustard is cultivated more extensively in the South than in the North, as it will grow where the climate is too hot for other greens. In the North it is usually grown only in home gardens for family use; the plants run to seed in midsummer, so seed must be sown very early in the spring. They are ready for use in May or June. Some of the new improved varieties of curly-leaved mustard are among the best of pot-herbs. In the South, the Southern Giant Curled Mustard is much used, taking the place that lettuce and spinach fill in the northerly sections. The Chinese Broad Leaved is a vigorous variety which gives a large amount of foliage. It is easy to grow, and even in the North, if the soil is warm and sandy, seed may be sown in the fall and the plants will be ready for use early in the spring, even though the seeds do not start sprouting in the fall. The seed escapes easily and sows itself in unoccupied areas and spreads rapidly. So, if it is not carefully watched to prevent too general seeding, it can readily become a troublesome weed.

DANDELION.

Everybody knows the wild dandelion, and almost everybody likes it as a pot-herb, but only those who have eaten the improved garden varieties, know its real possibilities. Although the dandelion is perennial, it is treated as an annual for the best results in cultivation, and the seed is sown in early spring and the crop either harvested that fall or allowed to remain in the ground until the next spring. It will grow anywhere, and often persists in growing in its wild type where you don’t want it; but if you want plants with large, cut or frilled leaves, you will see that the soil is rich and deep, and that the plants have good tillage all the season through. The leaves of these varieties are not only good to eat, but they are extensively used for garnishing. If they have been properly cared for, the plants will often measure 12 to 20 inches across, with a crown or rosette of dense foliage.

Dandelion seeds are usually sown where the plants are to stand, although occasionally they are sown in seed-beds and transplanted. As soon as they have made a fair growth they are thinned to about one foot apart: the distance between the rows will depend upon the sort of cultivation the plants are to receive. Hand tools require less space than horse tools, and hand-hoeing less than wheel-hoeing, with more labor and less returns. If the plants are allowed to stand through the winter, they are ready for the market very early in the spring when the demand is briskest and the prices best. In harvesting, the plant is cut off just below the rosette and the roots must then be plowed out so that there is no danger of the herb becoming a weed. It is not worth while to try to sell the small plants, but they should be cut off, to prevent them going to seed and becoming a nuisance. Some growers take the roots up and put them in forcing house or hot-bed for growing greens; or, they may be forced in the dark, which gives white or blanched leaves. This same effect may be obtained in the field by tying up the leaves, thus securing a blanched crown just as is done with endive. We owe much of the improvement of the dandelion to the French.

PURSLANE.

Purslane, or, as it is more generally called, “pusley,” is another herb that the French growers have greatly improved. The common pusley weed is a weak, trailing plant, but the French, cultivated variety stands up stiff with large leaves and juicy stems. It grows easily in any good garden soil, matures quickly and is not hurt by warm weather. The seeds are sown early in the spring and there is little danger of the cultivated sort sowing itself and becoming a pest.

There are some other varieties of greens; but this book aims only to treat of those which are generally grown and for which there is a sure market each year.

CHAPTER XVIII.

SALAD CROPS.

Salad crops are close kin to pot-herbs. But a salad is eaten uncooked, while pot-herbs are boiled. Some plants are used both ways, but they are then classed according to their most general use. Salad crops need a cool, moist soil and quick continuous growth. As has been frequently said before, (but not too frequently,) this can only be obtained by having the soil in good condition and plenty of plant food in a shape that the crop can eat. Salad crops need plenty of water, clean, thorough culture, and a good deal of prompt attention, but they mature so rapidly, that the demands are not really excessive. Having supplied their needs, you must, thereafter, depend upon the weather to help you perfect your crop. If you get dry, tough, wilted salad crops, you need not take the trouble to harvest them, for nobody wants that sort; and that is the only kind you can raise if you neglect them.

There is no pleasure like the ever-new exultation and joy of seeing the things we ourselves have planted come up; and these lovely colored shoots, springing from the brown earth, serve to renew our faith in the bounty of Nature and the loving order of the world—as well as to fill our pockets.

LETTUCE.

The most popular salad crop is lettuce, a hardy, short-season, companion- or succession-crop requiring moist, rich, mellow soil, and plant food in quickly available form. It is easy of culture and is chiefly grown in the open, though the demand for it has increased to such an extent that it is started in hot-beds or forcing houses that it may be earlier on the market. You can get it in about five weeks. Coolness and continuous growth are necessary to prevent toughness and bitterness. It is little grown in the summer, though the Cos variety can stand the hot weather very well, if the soil is moist and cool. Lettuce does better if transplanted and for that reason it is usually sown in seed-beds; in transplanting, it is usual to cut off the top third of the leaves, unless the seedlings are very stocky; but the mid-season and later crops may be sown where the plants are to stand. Fall lettuce should be sown in late August or early September, and, as it is easier to control soil conditions and to get quick sprouting in a seed-bed than in the field at that dry time of year, it is better to use the seed-bed. At any time lettuce does best in a soil that is loose and “warm,” that is known to gardeners as “quick.” Heavy, clayey soils are not adapted to lettuce, so see that your soil is pulverized and well fertilized before the seeds are sown. It has been found to pay well to treat the soil with nitrate of soda after the plants are set, because of the more rapid growth. The soda is applied dry, at the rate of two or three hundred pounds to the acre, and then raked or tilled in. Lettuce seed is sown thickly and the plants thinned, as they become edible, to about a foot apart. The thinnings make excellent “greens.” The rows are usually 8 to 12 inches apart.

When grown as a succession-crop, lettuce may be followed by cabbage, early cauliflower, celery and other things. Or, it may be grown between the cabbages and cauliflower as a companion-crop, since it matures before either, and leaves the land to those plants when they need all the space. Seed may be sown successionally until warm weather, and you may count upon 1000 plants for each ounce of seed. There are three well-known tribes: head lettuce, cut or curly-leaved, and Cos, and a fourth variety little known, called narrow-leaved lettuce. There are about 100 varieties. Field-grown lettuce has few enemies.

ENDIVE.

Endive is a summer and fall crop, thriving at a time when it is not easy to grow lettuce to perfection.[7] It is, therefore, a good addition to lettuce, and its culture is largely the same, though endive takes longer to mature than lettuce does. Endive matures under proper care about fifty days after the seeds are sown. If seeds are sown in June the plants will be fit for table use in August or September.

Endive requires about the same sort of soil as lettuce, the same tillage and the same general treatment. The plants should stand about a foot apart each way to make cultivation easier. It is sometimes sown in cold-frames, but just as often in the open field, and successive sowings will give successive crops, but that which gets its start during hot weather is not satisfactory. The inside leaves of the crown are usually blanched by tying them together near the tops for two or three weeks before the plants are ready for market. The blanched sort brings a better price. The disadvantages of blanching are that the plants fade and decay quickly unless used at once, and if rain or damp weather follows the tying-up, there is great danger of decay while in the ground. So the plants must be examined occasionally to see that they are doing well. When endive is used as a pot-herb, as it sometimes is, it is better to pick the new young plants before they have time to head or can be blanched. The coarse, outer leaves of the plant are apt to be bitter and tough, so that only the leaves of the crown are used for salads.

With all these crops you can see why nearness to market is so important—even though the land is higher priced.

CHICORY.

Chicory has various uses and is now quite largely grown in gardens. As a salad plant only the tender, blanched leaves of the crown are used. The outer, green leaves are often used for “greens,” like dandelion. Chicory is not a surface feeder like most salad plants, but is grown as a root crop the same as carrots or parsnips. The soil must be deep, that the roots may come to perfection by fall; cuttings of leaves may be made during the season. The roots may be left in the ground over the winter. Chicory is really a perennial, but under cultivation it is better to grow a new lot of plants each year. When wanted for winter use, the strong roots are taken up in the fall, and buried in a sloping direction in a pit or cellar, with the crown of the plant showing an inch or so above the sand or earth. The growing-place must be kept dark, and in a few weeks the small, prized leaves begin to show. When chicory plants are covered, crowns and all, with about two feet of manure, they develop heads resembling lettuce heads. The young, tender roots of chicory are eaten as beets or carrots are, while the dried root is extensively used in place of coffee. This accounts for the increased area devoted to chicory in this country of recent years; it is less injurious to the nerves than coffee.

CRESS.

There is a delicate “bite” and piquant flavor to cress, that makes it a favorite for salads and for garnishings. Of the three kinds in general use, the water-cress is probably the best liked, but to bring it to perfection it is necessary to have a running brook of clean, cool water. To grow it in a drain is a good way to get typhoid fever. It is a perennial, and readily propagates itself when once it has got a start, while the grower can increase its spread by scattering seeds along the brookside, or by planting bits of stems in the mud. When once established it will care for itself, and gives the grower no trouble. Although it does best along the sides of running streams, water-cress will grow anywhere if it can get moisture enough, even though not covered with water. Any moist, shady garden spot will do, if it is frequently watered, and gardeners often use abandoned hot-bed pits, where the hose can be turned on the plants daily.

Two women made a nice profit by sending fine water-cress, packed in oiled paper and cardboard boxes, to select customers by mail.

Common garden cress is a cool-weather, short-season annual, whose seeds may be sown early in the spring in a cool, rich soil, as its whole value as a salad plant depends upon its quick, vigorous growth. The plant runs quickly to seed in hot weather, or if left in the ground until late in the season. It is easily grown in pots or boxes in the house in winter; or, if wanted for fall use, the seeds may be sown in late summer and in early fall. Under ordinary conditions, the leaves are ready for use about six to eight weeks after seed is sown. There are a number of varieties of the garden cress; the sort with curled leaves being most in demand. It is not so well known here as in Europe. The third variety, known as the upland or upright cress, is perfectly hardy and common to all parts of the United States. In cultivation it is usually treated as an annual or as a winter perennial. Seeds may be sown late in the season, when the young plants will be ready for use early in the spring; or, they may be sown in the earliest spring and will be ready for use about fifty-two days after sowing. If grown through the summer they are apt to be bitter and tough, unless grown in a shady place. The upland cress resembles water-cress in flavor.

CORN SALAD.

Corn salad is not so well known here as in Europe, where it is highly prized as a fall and winter salad and as a pot-herb. It is a cool-season crop, grown as lettuce is. It is hardy and may be sown as early in spring as the soil can be worked. It comes to maturity in six or eight weeks, producing a bunch of leaves something like spinach. It may also be sown in the fall and protected in winter the

same as spinach, so as to have very early plants in the spring, or, if sown late in the summer, it will give edible leaves in the fall, and in a mild, open season, will nourish all through the winter. In warm weather or dry places, it soon runs to seed. It is very easy to raise corn salad in any cool soil, and an ounce of seed will give from 2000 to 3000 plants, which should stand about six inches apart in the rows.

PARSLEY.

Parsley is the most popular of all the garnishing herbs, and requires no special care from the gardener, so long as it is planted in a cool, moist soil. The leaves are used for salads and for flavoring as well as for garnishing. Parsley seed is slow growing, and unless the garden soil is in excellent tilth and moist to the very surface, it is better to start the plants in a seed-bed. Although the plant is biennial, the foliage is usually gathered the first year and the plant destroyed, unless seed is wanted. In all these green things, it has been found better to adopt the annual treatment rather than let them develop into biennials or perennials, though that may be their natural habit: we can improve the nature of plants, animals and men.

SALAD CHERVIL.

Although salad chervil closely resembles parsley and may be used the same way, it is very little known in this country. It requires about the same culture as parsley, and is easy to grow in cool, moist soil in spring or fall. It does not thrive well in our hot summers, but with very little protection from cold-frames or even from brush, it can be carried safely through the winter, if the weather is not very severe. The curly-leaved variety is the most popular, whether used as garnishing or seasoning. The salad chervil grows nearly two feet high when it reaches full maturity, but the young foliage is the most prized. It will give leaves for cutting in six or eight weeks after the seed is sown.

CELERY.

All garden or field crops are divided into two classes, those whose seeds are sown where the crop is to grow; and those whose seeds must be planted in special conditions, such as seed-beds, hot-beds or forcing houses. Celery is always a seed-bed crop, and occasionally a hot-bed or forcing-house crop, according to the time when the grower wishes it to mature. It requires a cool, rich, very moist soil, in excellent tilth, where surface tillage is maintained throughout the whole season. Although good celery may be grown on uplands by means of extra care and attention, it usually grows best in rich, moist, bottom lands. Reclaimed marshes, whose soil has been pulverized and fertilized, are ideal celery plots, because there the moisture is sufficient even during the heat of summer. Celery cannot stand exposure to the direct heat of the sun, and on exposed places many growers find it necessary to shade the crop.

Celery seeds are very small and slow to sprout and are sown broadcast or in rows. If in rows the sowing is very shallow. The seedlings are tender and delicate, so that it is only in a well-prepared seed-bed that the plants can be satisfactorily raised. The site of the bed should be selected with great care, so as to protect it from hot or dry winds, and to make it convenient to water it every evening. Celery requires a great deal of moisture. The soil must be in such excellent tilth that it will hold moisture up to the very surface without the help of a mulch. Some growers do use a mulch in growing celery, but it makes the delicate seedlings so much more delicate that the loss from sun-scald upon transplanting is likely to be heavy. If you do use a covering of any sort, be careful to begin to remove it as soon as the plants begin to grow, and take it all off before they are up enough to be transplanted. But if you make your seed-bed carefully, you will not need a covering for it.

Even when you have taken so much pains to start your celery crop, the work is by no means done. To secure good, strong, stocky plants, they should be transplanted once or twice in the seed-bed before the final transplanting to the garden. It is essential in North Carolina, says Prof. Massey, to transplant celery once before setting in field or garden. This entails so much labor, that many growers are now using the thinning process in place of these various transplantings, and even in the seed-bed the young plants are thinned to stand two to three inches apart and the tops are sheared if they grow tall too soon. The plants may be safely cut back a third or even a half of their growth. In small garden plots, shears or a sickle may be used, but, in the large fields, growers generally use a scythe.

There is usually a good deal of loss in celery seed, so it is well to sow it very thickly, and then you may reasonably expect from 20,000 to 30,000 plants to the acre. An ounce of seed will plant about 200 feet of row, and if good, should give from 5000 to 10,000 plants, although where losses are very heavy the yield is frequently only 2000 to the ounce of seed. One pound of seed should give plants enough to set out four or five acres.

Celery is grown both as an early-season and as a late crop, depending upon the location of the plot. On the higher lands, it is either an early or a succession-crop, following early cabbages, lettuce or other short-season crops. But on rich, bottom lands, it is a whole-season crop, as the land there is too wet to be worked early in the spring. Some growers raise two or three crops of celery in a season from one plot, the later or main crop being planted between the rows of the early crop. As celery may be set out as late as the middle or last of July, even in the Northern States, the main crop does not interfere with the early crop, which may be set out as soon as the ground is ready.

For two crops, the soil needs more attention than where only one is raised, because cultivation and fertilizer must add and preserve the moisture which is natural to the lower levels. Celery needs potash and nitrogen, and these foods are supplied by unleached wood ashes and well-rotted stable manure. Coarse, new manures must not be used, as they make the soil coarse and also cause weeds. Only old, fine, well-rotted manure will do for the celery bed.

When tillage is given the growing plant, care must be taken not to disturb the roots. The soil may be stirred only at the extreme end of the tiny rootlets, and if fertilizer is applied it must be placed at the same point. Some growers make tiny trenches between the rows and cultivate and fertilize there. Celery is one of the crops that call for thoroughly intelligent care. In many localities where the weather is hot or dry, sub-irrigation, by means of tile-drains, has supplied the needed moisture for this thirsty crop.

There is an entirely new celery culture in the sterile sand of Florida by commercial fertilizer; but that is a subject by itself. The Florida Experiment Station will give particulars.

The plants should be four or five inches high when transplanted and the stems stocky and green. They are set from 10 to 12 inches apart in the rows and the distance between the rows depends mainly upon the method of blanching. To bring a good price in the market, celery must always be blanched, although many growers prefer it in its natural condition for their own use.

Celery is blanched in three ways: Blanching by boarding; by banking up with earth, or by blanching in storage pits. Boarding is generally applied only to summer celery, as it does not afford protection enough for plants left in the field after early October. It is the simplest and most economical method of blanching, and where used, the rows may be two or three feet apart to admit of horse cultivation.

For blanching by boarding, planks 12 to 14 feet long, one foot wide and about an inch thick are preferred. These planks are set on edge on either side of the row close to the root crown of the plants, and tipped until they rest against the tops of the plants with their edges only two or three inches apart. Either wire hooks or cleats nailed across the tops are used to keep the boards in position. This boarding or blanching process is begun as soon as the plants are tall enough to show a few leaves above the board. As the stalks shoot up in search of light, the leaves fill the spaces between the boards and exclude light from the stalks. Great care must be exercised in warm weather that the plants do not rot at the heart because of too great moisture. Experience will teach you that it is well to get good lumber that may be used many seasons, rather than cheap boards which will warp or crack in one season.

Blanching by banking with earth, often gives a better quality of celery, but it is much more expensive and cannot be so safely used in summer, as it tends to rotting at the heart. It usually requires two or three bankings or “handlings,” as they are called, during the season. The first is given when the plant has spread so as to make a head about eighteen inches across. Then it is gathered in the hand and held, while earth is banked up around it about two-thirds of its height. In ten days or a fortnight this is done again, and in the very tall varieties once again. When this method is used the rows are from three and one-half to four feet apart. Of late years large growers use a “celery plow” for banking.

When celery is to be blanched in storage it is usually “handled” once while in the field, so as to start the process of blanching. Afterwards the plants are placed so close together in pits or sheds that the blanching goes on until the crop is ready for market.

There is another method of blanching celery which is particularly successful in small areas. It consists of growing the plants so close together that the light is excluded and the crop blanches as it grows. It is then grown as close as six or eight inches apart either way. This is called the “new celery culture,” and is successful where the hose can be freely used to supply the necessary moisture.

Storing.

But the care necessary for growing celery does not end even with the blanching. It extends to storing, which is also important to the crop. There are several well-known methods, chief of which are storing in outside pits or cellars and storing in celery houses.

Usually the outside pit or cellar is a temporary affair and a very satisfactory one is built like the regular vegetable pit: the way to make that is given in another chapter.

If celery is to remain crisp and juicy, it must make a very slow growth all the time it is in the store-house, and should be kept just above freezing point.

When you prepare your celery for market, be sure to clean it thoroughly. This may be done by washing, or it may require scrubbing, but be sure to have it clean. Remove the outside leaves and trim the roots down to a point, then pack in boxes or trays. And right here comes in another reason for studying your particular market, because the number of bunches of celery packed in a box or tray—and even whether you use a box or a tray—depends upon the market you supply. It varies with different markets.

In the “new celery culture” where the plants are set so closely together that they blanch themselves, it takes 150,000 plants to an acre. This method of growing requires greatly increased quantities of fertilizers or results will be very unsatisfactory. The dwarf varieties of celery are most in demand, and the favorites for summer and fall are White Plume, Golden Self-Blanching and Kalamazoo; while for late winter and spring, Boston Market and Arlington are standard sorts.

The chief diseases are leaf blight and leaf spot and the fungi that attack the plants in storage. For leaf blight, dip young plants in weak solution of copper carbonate, and treat the young growing plants twice a week. It is well to read up on diseases; and for blight read the Department of Agriculture Report, 1886, pp. 117-120; Cornell Bulletin 132, pp. 203-205. To avoid leaf-spot, select seed carefully, treat it with Bordeaux mixture while in seed-bed, and continue its use if you fear an attack. Read New York Bulletin 51 and Cornell Bulletin 132. For dealing with the diseases that develop during storage, read Cornell Bulletin 132, and Bailey’s “Vegetable Gardening,” p. 229. If you wish to know all that celery specialists have discovered about this crop, read Greiner, Hollister, Rawson, Vaughan, Stewart, Von Bochove and Crider. These books may be found in some good public libraries or will be supplied by our house.

Understanding all this attention and care, you can easily see why there is big money in a successful celery crop, and why Florida’s flat sand lands are making their owners rich raising celery—or raising rents and prices.

CELERIAC.

Celeriac is a form of celery, or at least is a very near relation to the real celery, and requires about the same soil preparation and the same conditions and tillage. Celeriac is frequently sown where it is to stand, but as the seed is as slow to sprout as celery, this is not really a wise plan. Sown in a seed-bed and transplanted, the crop gives far better results. In celeriac it is not the stalk but the enlarged, tuber-like root which is eaten, and the plant requires no blanching. It may be eaten raw in a salad, or cooked, as you like. Good roots should be from three to four inches in diameter and they may be kept through winter by packing in sand or moss as many other vegetables may be kept. Celeriac is sown in the same quantities as celery seed, the rows being only far enough apart to allow of cultivation, and the plants from six to eight inches apart in the rows. Being of a dwarf nature the close planting does not cause the plant to over-shade itself.

FOOTNOTES:

[7] NOTE.—Fullerton says that the narrow-leaved, deeply serrated plant called endive in this country, in France is the chicory or succory known to all Americans as a roadside weed with beautiful blue flowers like a very open aster.

CHAPTER XIX.

PULSE CROPS.

Peas and beans are the pulse plants, and although they are cousins they are widely different in their requirements. In this respect peas and beans resemble children, who though in the same family, do not always thrive under the same conditions or do best with the same treatment. Both these crops are leguminous, and, therefore, capable of storing the nitrogen from the air in their roots, and thus enriching the soil where they grow, yet it is often necessary to apply nitrogen to secure a quick start for early crops. This is especially true where the soil has not before been used to grow leguminous crops. The more we study plants the more we learn about children and the more likely are we to recognize the close relation between all forms of life.

PEAS.

Peas are a partial season crop, and do not require very rich soil. They are so hardy that the seed may be sown where it is to stand, even before frosty weather is wholly gone. It is best to plant the seed from three to five inches deep, which allows the roots always to be in cool, moist soil. A very rich soil tends to make the crop run to vines and leaves, so that a light soil is necessary, particularly where the crop is to be an early one. Peas should be early or late, because they like cool weather, and are apt to mildew if carried over into hot summer days. The fall crop may be planted early in August even in the Northern States. The plants should be from three to four inches apart in the rows. It takes a pint of seed, of the small varieties, for 100 to 125 feet of row, or one to two bushels to an acre. Where peas are grown in large quantities in a field, for canning, the seeds are sown broadcast and then it requires from two to three bushels to an acre. For early crops the dwarf varieties are preferred as they mature so quickly, and the tall, climbing varieties are planted for late crops. Planting and tillage for both kinds are the same. Peas should be planted in double rows only six or eight inches apart, so that the one row of supports, either brush or chicken-wire, preferably wire, may serve both rows in tall peas, while the dwarf plants support each other. Between each two pairs of rows the space should be wide enough to admit of tillage.

Very few farmers understand the value of peas to the soil or as stock feed. This is especially important for farmers of the Northern States, for peas will grow where corn will not, because of the cold; they do not need much soil preparation or after-tillage; they yield a good crop of forage that is excellent for fattening; they take any place in a good system of rotation of field crops, although it is most satisfactory to follow them with wheat; they may be sown at intervals of ten days, from very early in the season to very late, and when the crop has been harvested the ground is in better condition than before it was planted.

In Europe they grow peas with delicate pods, called edible-podded or sugar peas, which are eaten as string beans are, but these are almost unknown here. The two kinds of peas used here are the wrinkled-seed pea and the smooth-seed pea. The wrinkled variety is the best, but it is more likely to decay when planted very early. Both sorts of seed are found in dwarf and tall varieties of pea. The most popular of the very early peas are First-of-all, American Wonder, Philadelphia, McLean Little Gem, Daniel O'Rourke, and Blue Peter. Among the late peas the Marrowfat, Champion of England, Stratagem, Telegraph and Telephone are leading favorites.

Peas start so early that they do not suffer much from weeds, unless the land is infested with the annual wild mustard. This will choke the peas, but it may be destroyed by a spray made of eight to twelve pounds of copper sulphate dissolved in 50 gallons of water, when the plants are only a few inches high. This solution will not materially injure the peas.

The insect enemies are the "pea weevil" or "pea bug"; the pea moth, and the pea louse. The pea weevil lays its eggs on the outside of the pod, and the grub, on hatching, eats its way into the pea and while hiding there changes into a beetle of a brownish-grey color, and about one-fifth of an inch long. It does not come out until after the seed has been sown in the spring. This beetle spoils the pea for seed and even to a large extent for stock feed. Where the weevil has attacked the peas, it is the custom to place the seed in air-tight vessels or rooms and fumigate with bisulphide of carbon for several days. The proportion is one pound of bisulphide for every hundred bushels of peas. Great care must be exercised in using bisulphide, as it is highly explosive and very poisonous. But only the careless or stupid need get hurt; so there's no danger for you. Get explicit directions from your nearest Experiment Station, and follow them closely.

The pea moth attacks late varieties of peas most severely, and as no remedy yet used has succeeded in destroying the pest, or even in materially reducing its ravages, the best thing is to sow early varieties of peas and so escape its worst effects. It is seldom seen in moth form, but is common enough as a "worm," or small, whitish, somewhat hairy caterpillar, about a half-inch long. It lives inside the green pods and eats ragged-edged holes in the peas, which it then fills with excrement or waste matter.

The pea louse is pale-green in color, and clings in great numbers to the tips of the shoots, and sometimes covers the whole plant. It attacks whole areas of peas sometimes, and becomes a serious pest. However, its hold is slight, so that it may be easily knocked off. In small garden patches they are brushed off in pans and burned, while in large fields of peas what is called a "brush-and-pan" device is used, followed by the cultivator, which buries the lice or aphids.

To find out more about the culture of peas, get Farmer's Bulletin No. 224, U. S. Department of Agriculture, Washington, D. C., and for the best methods of dealing with the crop's enemies read Delaware Experiment Station (Newark, Del.) Bulletin No. 49.

Pea cultivation was recorded two thousand years ago.

BEANS.

All the well-known varieties of garden beans are tender to frost, needing a warm season and a sunny exposure. The seed is not sown until the weather is thoroughly settled and the soil in excellent tilth; then it is sown where the plants are to stand. The favorites in this country are the dwarfs; the chief advantage of the dwarf types is the saving of expense in supports, and the greater ease of cultivation. The early crop is usually eaten as string beans, though the best “string” bean is the kind that has no “strings to it.” This variety breaks off with a clean snap and is often known as “snap” bean. Beans that are well suited to be eaten as string beans have thick, fleshy pods and very little fibrous tissue. In order that string beans may be of the best quality, the crop must make a quick and uninterrupted growth. A succession of beans may be had all summer by planting at intervals, and late in the summer season a new crop may be planted for late fall use. String beans are always in demand; and now, because of the southern crops, the markets of large cities are seldom without them all the year around.

Beans, like peas, are nitrogen gatherers, but if the ground where they are to be planted has not been used for peas or beans within a year or two, it is well to apply a little nitrogen at first to start the growth. The land should really be prepared for beans the season before you plant them, because new, fresh or coarse stable manure applied when planted, will make the crop rank, without increasing the yield. This is especially true of Lima beans. Spread the manure the fall before, so that it will have done its work before the spring planting begins; if more fertilizer is necessary, use some of the quickly available commercial fertilizers, those rich in potash or phosphoric acid being the best. The soil should be harrowed at least twice before planting and thoroughly pulverized. This puts the soil in good tilth and prevents the growth of weeds. Through the whole season tillage should be frequent enough to prevent weeds getting a footing or a crust forming about the roots, but the plants should not be cultivated while wet with dew or rain, as that renders the crop liable to spore diseases.

LIMA BEANS.

Late Lima beans demand such a long season and such continuous growth, that it is not always advisable to try to grow them in the Northern States, especially not the true Lima beans. The Sieva or Carolina bean is a Lima that may be successfully raised in the Northern States if due attention is paid to soil and exposure. It is not so high a climber as the large, true Lima, and therefore matures before the nights get too cool. It is a comparatively early crop, quite hardy for a Lima bean, truly annual, with thin, short, broad leaves, and a lot of papery pods much curved on the back, which burst open when the beans are ripe. These beans or seeds may be white, brown, or marked with red, but are always small and flat. Challenger is the favorite brand of Sieva bean. The true Lima is larger, whiter, and may be speckled with red, brown or black. The pods are fewer, thicker, and do not split when the seeds are ripe, and the vines are more easily injured by a touch of frost. Both the true Lima and the Sieva Lima may now be had in dwarf varieties.

String and Lima beans are not the only sorts in common use. The others are not picked until fully ripe, when the pods cannot be used. They are known as “shell” beans, and there are several kinds, all in high favor. These are mostly of the pole variety and mature late in the season. The preparation of the soil and the general culture are the same as for dwarf beans, the Scarlet Runner and White Dutch Runner.

There are more than 100 varieties of beans and no one book could give in detail all that is of interest concerning them, but the gardener who wants to know more of his bean crop may read Bailey, Bulletin 87 Cornell Experiment Station, and Cornell Bulletin 115.

Bush beans are sown in drills, 18 to 20 inches apart to admit of easy and frequent tillage, which is necessary to preserve moisture and destroy weeds; the plants stand from five to ten inches apart in each row. One pint of seed will sow from 75 to 125 feet of drill, according to the variety of bean used, or at the rate of one bushel up to five pecks of seed to the acre, when sown in drills. Fall, or climbing beans, and all Lima beans, are sown in hills, four or five seeds to a hill, and the hills are three to four feet apart.

Pole and Lima beans need supports and when poles are scarce you may put strong stakes in the ground at distances of 10 to 12 feet, and then run two rows of wire from pole to pole, one row near the ground and one near the top of the stake. Then from the top to the bottom wire, run cords, up which the beans may climb. In small, home gardens, growers often sow Lima beans in a semicircle of hills around one stake and then run cords from each hill to the top of the stake; but this method is not suitable for a large area.

But climbing beans, especially Lima and Scarlet Runner, can be ornamental as well as useful, and the wise gardener looks out for all such possibilities in his crops. If you have an old fence or unsightly building, plant your climbing beans against it, feed them well,

and they will make a good growth of green vines, which will be a pleasure to look upon, at the same time that they give a good yield. This is true intensive farming, as you are getting all there is out of your ground, and at the same time making your place more beautiful at no added expense, save the use of additional intelligence.

There is still another point to remember in planting Lima beans, and simple as it may seem, it is really one of those tricks of the trade which make all the difference between profit and loss. Plant your Lima beans _eye down_. Other beans will stand for anything in the way of planting, but Limas are particular and insist upon having their peculiarities considered. You have seen people just like that, and you know that a little special attention brings its own reward. It is the same with Lima beans—or indeed with any other crops—give them what they want and they will give you what you want in return. That is nothing more than a fair bargain, and the love of a bargain is ingrained in the American nature.

Commercial bean growing is a comparatively recent business, dating back only to 1839, although beans have been used for human food for many centuries. This branch of farming in New York State alone means the annual production of several millions of bushels of dried beans for commercial distribution.

The Northern States, Canada and California, are the chief bean-growing sections; in warmer sections the crop suffers severely from pests, so that it is not profitable to raise it. Southern bean growers use northern-grown seed to avoid the ravages of the weevil. Even in New York State some sections suffer more from this pest than others; beans grown in the northern counties being practically free from attacks. If you mean to grow beans by the acre, you will do well to read up more fully in Department of Agriculture Bulletins and in Bailey's "Cyclopedia of American Agriculture," Vol. II.

The chief disease from which beans suffer is anthracnose, which even the beginner may recognize when it has reached the stage where sunken brown spots appear on the pods; and when these spots have a tiny pink centre, you have seen the spore at work. The best known means of fighting it, is to select clean healthy seed, carefully hand-picked; go over the field as soon as the plants come up and weed out the affected ones; spray thoroughly with Bordeaux mixture[8] to which has been added resin soap. The compound should be as follows: Bordeaux mixture:—1½ pounds vitriol, 1 pound lime, 12 to 15 gallons of water. Resin soap:—½ pound resin, ¼ pound crystallized salsoda, 1 pint water (boil until clear brown solution is secured, then add to Bordeaux mixture). Apply first when the third leaf of the seedlings is opening, and repeat at intervals of ten to twelve days or after rain has washed the mixture off.

[Illustration: THE RENT PAYER.]

FOOTNOTES:

[8] NOTE.—Unless the under surfaces of the leaves as well as the upper surfaces be kept coated with the spray, Bordeaux will be of little avail. For the commercial grower of dry beans, spraying is not advised.—Samuel Fraser.

CHAPTER XX.

SOLANACEOUS CROPS.

This is a big word, but it means only that these plants belong to the nightshade family.

This division takes in tomatoes, eggplant, peppers and husk tomatoes. These require all, or nearly all, the season to mature, and they keep on making growth, particularly in the North, until killed by frost. They are all seed-bed crops requiring a great deal of quick-acting fertilizer, especially when they are young, and to secure a heavy crop you must give them an early start.

They are really of the same family as the potato, yet they are not grouped with that crop, because the parts eaten are the fruits which grow on their stems and branches, rather than the thickened stem or "tuber." They are hot-season plants and are usually grown in hills.

TOMATOES.

In almost all parts of the United States the tomato is easily grown; yet it requires a long, warm season, and soil in excellent tilth for best results. The seed is sown in a seed- or hot-bed, and the plants are allowed to grow from four to eight weeks before transplanting to the garden, although they may be transplanted once or twice in the seed-bed to secure free and stocky growth. For the small home garden the plants are usually handled in pots, but for commercial purposes they are planted in small flats not more

than 12 inches square, holding about two inches of soil. The earlier they are started the better, because they are less likely to suffer from fruit-rot and frost if they fruit early.

In the North, you must have vigorous, stocky plants, well in advance of the season, and a warm quick soil, to get a good crop of tomatoes. Too much fresh stable manure will cause rank vine growth and delay fruiting, so that the soil should be fertilized a season in advance and the manure thoroughly rotted. At the time of planting it is well to apply a light dressing of nitrate of soda, as this gives better results than twice the application when given later at intervals up to August.

At the South, tomatoes are grown in frames covered with unbleached sheeting by night and during cold snaps, but in the day this covering is rolled up and the plants are hardened by the air. Although tender to frost, the tomato vine is a fairly hardy plant, and will stand earlier field planting than is sometimes given it, if it does not get frost. We have proved by experiment that the yield is greatly increased by early transplanting. There is a profit in that.

Tomatoes give earlier and better results where the vines are trained, but that is only possible in small gardens. Where the plants are grown for canning, little attention is given them after transplanting to the field. Losses from rot are of course much larger there, but this cannot well be avoided.

In small gardens they are pruned to a single stem. Strong stakes are driven into the ground and cords are stretched between them horizontally at top and bottom. From these horizontal cords you may run perpendicular strings, to one of which each plant is tied. Plants pruned and tied up in this way, may be placed as close together as 18 inches, while if left to spread they require from three to four feet of space.

By pruning is meant the pinching out of each side branch as it appears, compelling the plant to put all its growth into one parent stem. Some growers even go so far as to cut off the tops of the plant as soon as three clusters of fruit are formed. I have cut off whole branches where the vines were too thick, without apparent injury. All this decreases the quantity of fruit that each plant will produce, but it greatly increases the earliness of ripening, and the size and quality of the fruit. Besides, the plants may be grown so much closer that the loss in quantity is not so great as would at first appear.

Henry Jeroloman of New Jersey, known all over the country as the “Strawberry King,” has a tomato-planting trick that is worth noting. Mr. Jeroloman, by the way, raises about $5,000 worth from his eight acres annually, and he plants tomatoes at the foot of his grape-trellis posts and trains them to climb up the posts and along the trellis. And right here is where the real trick comes in: by training the tomatoes to climb up instead of sprawling all over the ground, he is able to plant his low-growing crops, like beets or turnips, close up to the vines and lose no space. That is one of the reasons why his eight acres bring in more than the average farm of 100 acres. Your profit will depend upon similar devices for “working” the soil.

The best rack for supporting unpruned vines, is a cheap, rough and simple affair, constructed by the grower himself as follows:—Run a row of stakes on either side of your tomato bed and nail a light board to each row about a foot from the ground, so that the distance between the two rows will be about three feet. Across this lay narrow slats, loosely. The plants lop on the slats, the fruits ripen uniformly, and usually with a smaller percentage of rot than where they lie on the ground.

If your garden is situated where frosts are apt to come as early as August, you should plant your tomatoes against the south side of the house or out-building and cover them at night,—a point worth noting for all tender plants.

In “Vegetable Gardening,” Green suggests an ingenious yet simple method of raising enough tomatoes for family use where the season is too short to raise them in the field or garden. Get three or four barrels about the size of a coal-oil barrel, bore several holes in the bottom of each, then sink about one-third their depth in the ground in the warmest corners of your land.

When this has been done, fill each barrel about half full of fresh horse manure well tramped down, and pour over it a bucketful of hot water to start fermentation. On top of this put eight inches of good soil, then a mixture of well-rotted manure and good black loam in equal quantities up to about twelve inches from the top of the barrel. Heap manure up around the outside of your barrel. Plant, say three stocky plants in each barrel, trimming them to two shoots each. Tie one shoot from each plant to stakes or some nearby support, and let the other grow naturally over the side of the barrel. Give a gallon of water a day to each barrel and you will raise enough tomatoes in the season for a family of four or five persons.

The Iowa Experiment Station showed that untrained tomato vines gave the smallest yield and the largest percentage of decayed fruit; that staked vines gave a much larger percentage of sound fruit and the least percentage of decayed fruit of the whole

experiment; that hilling up did not give any striking results in any direction; and that, while mulching enormously increased the yield, it also greatly increased the tendency to rot.

Because tomatoes suffer so from frost, it is wise to hasten fruiting by every means, but if frost strikes before the fruits are ripe, the large green ones may be picked and placed in drawers or other dry, close places to ripen. Generally they color well and develop a good quality. If the fruits have not reached full size, the whole plant may be pulled with the fruits on, and hung upside down in a barn or dry building, and they will continue to draw nourishment from the plant and sometimes ripen.

From one ounce of seed you may expect from 2000 to 2500 plants; if planted in hills three by four feet apart, an acre will require 3630 plants. A large yield of tomatoes is from 12 to 16 tons per acre; the average is much below this. The favorite tomato in the American market is large, round and smooth, the Angular and other irregular-shaped varieties bringing a much lower price. Varieties run out so quickly that it is not advisable to give the names.

The friend that you make in the seed store will be able to keep you posted about such things—you can look in his eyes and tell if he is lying, which you can't do with a catalogue. Or you can ask the Agricultural Editor.

EGGPLANT.

You treat eggplants just as you do tomatoes, except that they need even greater care that the young plants are not checked in their growth, and a longer season. Eggplant is really a hot-climate crop, and so requires especial attention for early ripening in the Northern States. It grows best in the South, but does well as far north as New Jersey and Long Island. Further north it is seldom grown for more than home use.

Eggplant needs a long season, sunny exposure, a warm, loose, and rather dry but rich soil. It is started in the hot-bed and not transplanted until from six to ten inches high. It is such a finicky crop that if the plants are crowded or stunted even in the hot-bed, the yield is seriously reduced. For this reason, growers often start it in two-inch or three-inch flower pots, or in old, small berry baskets, as it is less likely to suffer a check when transplanted to the garden. Eggplants do not need so much moisture as peas or cool-season crops, and whatever fertilizer is applied must be quickly available. Perfect tillage is necessary from first to last.

Eggplants are set in rows far enough apart to admit of horse-tillage, from 3½ to 4 feet apart, and two to four feet apart in the rows, according to the variety of plant grown. The fruits are fit to eat when they have reached one-third their full size, and are desirable until they are fully ripe, when they lose their value as food.

Although the fruit may be left on the plant until fully grown, a larger crop is secured by picking before their full size is reached. For market, however, they must be well colored. The large varieties such as New York Improved and the Black Pekin bring the highest prices in the market, but it is difficult to grow them to perfection in the Northern States because of the short season. Some of the dwarfs, notably the Early Dwarf Purple, are more desirable. White eggplants are not popular, because they are usually an ugly yellow, while the striped and coiling fruits are regarded more as curiosities than as staple market products.

The eggplant is subject to several obscure fungous diseases, particularly in the South, and the only known remedy is rotation and destruction of the diseased vines. For the potato bug, which sometimes attacks eggplants, it is best to use Paris green, about one-quarter pound to 20 to 25 gallons of water, and plenty of lime. For leaf spot, use Bordeaux mixture. Get New Jersey Report 1890, p. 355.

PEPPERS.

Peppers are started in frames and when transplanted are set from eight to twelve inches apart in the row. They are cultivated just as tomatoes are, and, as they do not suffer from pests or diseases, the crop is more sure.

Peppers will thrive in a cooler season than tomatoes, and will even endure slight frost, but in all other respects they require the same treatment as tomatoes. They have only recently acquired any importance as a crop, and even now, their use in cooking being only semi-occasional, they are not very staple. Italians use them extensively, and as Italian communities grow, the demand for peppers will increase. We use them mainly for making pickles, for which purpose the small Cayenne, Chili and Cranberry varieties are grown. For stuffing, the favorite sorts are the large sweet peppers, Sweet Mountain and Ruby King. These peppers are not at all similar to the pepper-berries of commerce, which belong to other families.

HUSK TOMATO.

The husk tomato is an herb which produces a kind of papery skin containing a yellowish, glutinous berry. It is often spoken of as the strawberry tomato. It is very easy of cultivation on the tomato plan, although some varieties, notably the Cape Gooseberry, do not ripen well in the far North; the Dwarf Cape Gooseberry, however, does well as far north as Ontario. The soft, sweetish fruits may be eaten raw or cooked and are often used for preserves and pickles. There are several native species, some of which are called Ground Cherry.

CHAPTER XXI.

VINE OR CUCURBITOUS CROPS.

“Cucurbitous” is a fine large word, but you don’t need to learn it. All vine crops are annuals and are tender to frost, although all do not need a hot-bed start. They are warm-season crops, and in the Northern States most of them need a quick start so that they can ripen before the summer is past. Well-prepared soil and a sunny exposure are desirable. They transplant with such difficulty that they are usually sown where they are to grow, but if not, it is best to start them on sods turned upside down, or in pots or boxes. They are always a main crop and are planted in hills. There is very little difference in the cultivation of any of them, and if you know how and where to grow one, you will generally do well with the rest.

Where you fail, you may usually lay it to the fact that your soil was not in condition to give the young plants a good hold and to get a quick start. If your soil is well prepared, well drained and properly fertilized, you will have little trouble, unless it may be from pests. The way to fight those is to sow seed freely, and be content to lose the greater part of your possible crop.

Some growers who make a specialty of melons or cucumbers, plant squash and pumpkin seed very early in the field that the young plants may attract the striped beetle and give the farmers the opportunity to kill the pest before the real crops are taken from the frames. That is a method of deceiving the creatures, but the end justifies the means.

Unless you live where the climate is cold and the season short, you may plant squash, pumpkin and cucumber in the open fields where they are to grow. Otherwise start them in frames, as muskmelons are started. The land should be given the best of surface tillage, and every effort should be made to start the plants so well that the fruits will have set before midsummer. All these vine plants need much moisture in the soil and if the preparation-tillage be neglected, no amount of after-tillage can make up for the first loss.

Watch the vines carefully so as to prevent one fruit setting much in advance of the others. It is better to pick the first one off if it is much ahead of the main crop. Otherwise there will be no uniformity of size or quality. If your plants run too much to vine, pinch off the shoots and let the vigor go to fruit-making.

These crops often succeed as early crop and main-season crop, by starting one about two weeks after the other. Spade up the ground loosely for a space of a square foot or two, and mix light, loose earth or barnyard scrapings with it to make the hill. It is well to add a handful of fertilizer to the earth; but if it seems cold and hard, remove it altogether and replace it by light, warm soil. Of course in the warm, light soils of the South this is not necessary.

CUCUMBER AND GHERKIN.

There are almost no special directions for growing cucumbers if the general directions for all vine crops are carefully followed. Cucumbers are planted in hills, usually four by four feet apart, though for the large, late varieties they may be as far as four by six feet apart. An acre contains 2722 hills when the distance is four by four feet, and it requires two pounds of seed to plant an acre, or one ounce to 70 or 80 hills. That will allow four or five plants to a hill. Remember to plant freely if the striped beetle is at work near your patch.

As cucumbers are eaten when young, it helps the yield immensely if each fruit is picked as soon as it reaches the table state. You should go over the entire patch every two or three days at least, to see that no fruit is ripening at the expense of the growth of its little brothers on the vine. If you want to keep some for seed, reserve a whole hill for that purpose.

For the early-season varieties which are planted in flats or seed-beds, the Early Russian, a small-fruited sort, is the favorite. For the later sorts the White Spine, in various strains, is the standard.

Gherkins are simply immature cucumbers, very small in size; they are used solely for pickles, usually sweet pickles. The fruits of the West Indian or Bur cucumber are also called gherkins. The treatment is the same as for cucumbers, but the fruits are pulled as soon as fully formed. It is quite profitable to pickle them yourself.

On the average, an acre will yield 100 bushels of cucumbers for pickling, but this yield can be greatly increased by proper care and attention. Under the best conditions, 400 to 500 bushels to the acre are possible.

MUSKMELON.

The muskmelon is native to southern Asia and was grown by the ancients. The melon grows best in light, sandy soil in warm, sunny spots, although it is raised for market in many parts of this country, and as far north as parts of Canada. New Jersey is an important melon-growing State.

Melons are planted in hills from four by five to four by six feet apart, according to whether early or main-season crop. The early crop may be planted a little closer than the main crop, and is in the field two or three weeks ahead. The quantity of seed is about the same as that used for cucumber planting and the same treatment is necessary. There are about 1185 hills to an acre, and two or three good fruits to each plant is a good yield. The most important varieties are the cantaloupes, which have hard, warty rinds, and are little grown in this country; the nutmeg or netted type, extensively grown here, and the winter melons, which ripen late in the season and are as yet little known here. The leading varieties to be found in the American market, are Rocky Ford, Osage, Montreal Market and Hackensack, but the melon is so variable that only types, not varieties, are constant. Diseases and insects are the same as in cucumber.

WATERMELON.

Watermelons are even more uncertain than muskmelons, because of their need of a long, warm season; therefore, they are but little grown in the northernmost States, except a few varieties which will ripen as far north as southern Ontario, if both soil and exposure be warm enough. Watermelon needs such a long season, such a warm, well drained soil, such attention to detail, to come to perfection, that it is not a very profitable crop for the average gardener. In the past, the south Atlantic and Gulf States have held first place as watermelon centres, and are likely to continue in that proud position even though the mid-continental States have taken up the industry.

Seeds are planted where the plants are to grow, but all danger of frosts should be past. The best soil preparation includes fall plowing that the winter frost may help powder the earth. The hills are made by mixing several shovelfuls of well-rotted manure with the soil and then covering the mixture with some inches of fine, soft earth. Plant the seeds in this and see that the soil does not bake or crust. This can only be avoided by careful surface tillage. The cultivation of watermelons must be done solely with hand-tools, as the vines are very tender and the least injury to them affects both quantity and quality of crop. The hills are usually ten feet apart each way, and there are only 435 hills to the acre. It takes four pounds of seed to sow an acre. When grown in the Northern States, plants may be started under glass, but great care must be taken to avoid any injury or check to the growth, during transplanting.

Beginners often find it difficult to tell when a watermelon is ripe. There are three recognized methods, but to the practiced eye none of these tests are necessary. If a melon “thumps” right, that is, if it gives out a dull, flat, dead sound, it is ripe, but if it rings hollow or musical it is not yet ripe. The next test is the yellowish cast to the side that has lain on the ground, along with a hard, rough, warty skin in that place; and the third is the way the melon “gives” under pressure of the hand. The last test should never be applied to melons intended for the market, because it bruises them inside.

What is called vegetable citron in this country is nothing but a variety of watermelon with flesh too hard to be eaten. It is not the true commercial citron, which is the fruit of a tree like the orange or lemon.

Insects or diseases the same as in cucumber. If you must know more of watermelon culture, get Bulletin 38, Georgia Exp. Station.

PUMPKIN AND SQUASH.

Although so closely allied, pumpkins and squash do not usually cross, despite the common notion to the contrary. They are distinct types of the same family. The standard variety of pumpkin in this country is the Connecticut Field. The fruits are large, orange-colored and smooth furrowed. They are used to make pies for man and as food for stock, while to the small boy they are

chiefly useful as “jack lanterns.”

The pumpkin is often grown in corn-fields and in England they have a summer variety called vegetable marrow, which is in great demand, while our summer squashes, Crookneck, Scallop and Pattypan are also forms of the pumpkin. These are called bush squashes, and may be grown as close as three by four feet in the garden, while the regular pumpkin and squashes require to be planted eight to ten feet apart. It takes three pounds of seed to the acre for each, and a yield of two or three fruits to the vine is a large crop.

There are several leading types of winter or field squashes such as the Hubbard, Marblehead, Boston Marrow, Essex Hybrid, and Turban. To keep them through the winter they should be free from bruises or cracks, be fully ripe and have the stem on. A touch of frost injures them. They should be stored in a dry place with a temperature above 50° and placed on shelves or in shallow bins. Large growers have specially constructed, stove-heated houses for storing them.

A third type includes the Winter Crooknecks, Dunkard, Tennessee Sweet Potato Pumpkin, and some others. The culture of both squash and pumpkin is the same as for cucumber.

The insects from which they most suffer are: the squash bug and the melon louse. To rid the fields of the bug, keep them free from rubbish. Trap the bugs with bits of squash leaves and every day in spring pick off the old bugs. Read New Jersey Bulletin 94; New York Bulletin 75, and Florida Bulletin 34.

For melon louse read Kentucky Bulletin 53 as well as those already mentioned. Get lice in their winter quarters and destroy at first appearance. Use bisulphide of carbon as the bulletin directs.

Powdery and Downy Mildew are the worst diseases. For powdery mildew, spray with ammoniacal copper carbonate, and read Massachusetts State Report, 1892, p. 225, and Cornell Bulletin 31. For downy mildew, use Bordeaux mixture every eight or ten days, until frost, and read Massachusetts State Report, 1890, p. 211, and New York Bulletin 119.

CHAPTER XXII.

UNCLASSIFIED ANNUALS.

In this division of garden crops come sweet corn, okra and martynia, which have no relation to the other crops, and none to each other, except that they require about the same cultivation. They are all warm-weather crops and are grown for their immature fruits. They require “quick” soil, are not usually transplanted and demand little care, except good tillage.

SWEET CORN.

Although almost unknown in any other part of the world, in America sweet corn is one of the most important crops. One hardly ever sees even a small backyard garden without a few stalks of sweet corn, while the canning industry has grown to such enormous proportions as to require thousands of acres of corn every year. Sweet corn cannot be grown in the South unless the seed is gotten from the North every year. It thrives best in the crisp climate of the Northern States and of Canada.

This is the crop that gave rise to the famous joke at the “World’s Fair” in Chicago. The Englishman asked the girl in charge, “What do you do with so much corn?”

“Oh,” she said, “we eat what we can, and what we can’t we can.”

Afterwards Johnny Bull tried to tell the story. “So funny,” he said; “she told me that they eat what they can, and what they can’t they put in tins—why don’t you laugh?”

Sweet corn requires more attention than field corn, both as regards earliness and the proper development of each plant. For this reason it is planted in hills rather than long drills, and in warmer and quicker soil, with quickly available fertilizer. Ground that has been plowed deep the fall before, and fertilized with well-rotted manure makes a good soil; if the ground be hard or cold, a handful of commercial fertilizer may be added to each hill.

Although corn is a hot-season plant, it is practically a surface feeder, so it cannot withstand drought as well as potatoes or other crops. That is why it is well to plow deep and make a good moisture-holding bottom in order to get good corn of any kind. That is also the reason for the frequent surface tillage given the growing plants.

Seed is planted for the early crop as soon as the ground is warm enough, and as corn rots quickly either in cold or damp ground, it is well to plant freely. Coating with tar perhaps preserves it, at least from the crows. The idea is to get as many ears as possible from each plant, so give plenty of room, the rows being three to four feet apart, and each hill from two and a half to three feet apart. For early crops use Early Minnesota, Early Vermont, Cory and Crosby and other popular brands. The Stowell Evergreen is the standard for late crops. Corn may be sown successionally, at intervals of a week or two, either for the home garden or for market supply.

In growing for market, earliness should be borne particularly in mind. The whole profit in corn may hinge upon even one or two days' delay. In fact, where you are competing with many other gardeners, a half day may make a big difference. You can get ahead only by having quick and well-prepared land, planting the earliest varieties and giving the crop good tillage after it has begun to grow.

Some gardeners force early sweet corn by placing a handful of fine manure in each hill, stamping it down hard with the feet. Loose dirt is then kicked over it and sprouted seed planted—that is, seed that has been soaked in warm water until germination has really begun within it. This is a good method where the soil is moist so that the seeds may get a quick start, but it is no good in dry soil. The manure acts like an individual hot-bed for each hill of corn.

Where this plan is used, thorough culture must be given, or the corn roots will remain in the manure during growing time and suffer from drought.

Corn is not the only crop that is benefited by the use of the feet in planting. Wherever the soil must be compacted about the newly planted seed, the feet can be used to advantage. So true is this, that Peter Henderson, the well-known New York gardener and seedsman, wrote a pamphlet called "The Use of the Hands and Feet in Planting," which is sent free upon application. It is well worth reading.

When it first comes into the market, sweet corn usually brings 25 cents a dozen ears; that is the time for the wide-awake gardener to sell his crop. Later it may fall to five cents a dozen, and usually sells as low as 10 cents; there is no profit in that.

If you pick the first ears as soon as they are well set, the second setting will be much better for it. (Very small, immature ears are fine cooked or raw, to eat, cob and all, but our people are not used to that.) It takes about a peck of corn to plant an acre in hills, and, if well attended to, the plants should yield from 8000 to 10,000 ears to the acre.

The insects and diseases include wire-worms, cut-worms, chinch-bug and corn-stalk disease. Short rotation, including fall cultivation of the land, will check the wire-worms. See Cornell Bulletin 107. Treatment for cut-worms is fully described in Cornell Bulletin 104. Ditching, plowing and harrowing are bad for the chinch-bug and good for your corn. Read Ohio Bulletin 69, Kentucky Bulletin 74, and New York Report 15, pp. 531-533.

It would be fruitless to take up your time with a discussion of corn-stalk disease here, when you can get it all by simply sending for Nebraska Bulletin 52.

OKRA OR GUMBO.

Although okra is really a Southern States perennial, it is cultivated as an annual, the seeds being sown every spring. It is grown for its pods, which are cut while still young and tender, and are much used for soups and stews. Of recent years the pods are also canned and dried for use in winter.

Okra takes about the same treatment as sweet corn, the seeds being sown where the plant is to grow, except in the Northern States. There the seeds are often planted in boxes, pots or sods turned over, simply because the season is not long enough to ripen the plants. The real okra is a large-growing plant that must be planted from one to three feet apart in rows that are three to five feet apart, but the dwarf and early-maturing varieties that are grown in the North, may stand as close as one foot apart in the row. There are no important insects or diseases.

MARTYNIA.

Martynia is grown solely for its half-matured pods which are used in pickles. The plant needs a warm soil, sunny exposure, and much room, as it spreads over three or four feet. It thrives under the same cultivation as is given corn and okra, and may be planted in frames or in the open as soon as the weather is warm enough. It is annual and native from southern Indiana to the Gulf.

CHAPTER XXIII.

HERBS, SWEET AND CONDIMENTAL.

A great variety of plants, medicinal, flavoring and decorative, are herbs, but we will consider only those used for cookery and usually called “sweet herbs.” The very name brings memories of fragrant smells. If we cannot all say, “I know a bank whereon the wild thyme grows,” yet few who have ever known a garden are unacquainted with the odorous bed of thyme, sage and mint. Although there is not such heavy demand for them in this country as in Europe, yet their use is growing, the favorite being sage.

Sweet herbs may be divided, both as to culture and as to products, into two classes:—the annuals and the perennials: those grown for their foliage, and those for their fruits. All are easily grown and demand little attention, and though they may be bought at any drug store, yet they who have once raised their own herbs find a pleasure in them that they will not like to miss. Annuals and perennials may be grown together and a very little plot of ground is enough to grow them all. Choose a place where they will not interfere with plowing and cultivating and let them stay, planting the annuals in the same place each year, and renewing the perennials as soon as they begin to lose their aromatic qualities or otherwise to fail. The annuals should be sown every year, but perennials may be propagated by division of clumps. Discard all the older clumps and replant only the newer, younger portions.

Those that are prized for their foliage, such as sage, thyme, hyssop, mints, tansy, horehound and wormwood, are usually cut when the plant is in full growth before the stalks have become woody. Cut the stems near the ground, tie them in bunches and hang them to dry in the attic, if you are fortunate enough to have such a treasure-hole, or in some cool, dry place. You may also cut the herbage from time to time during the season, but this weakens the plant and necessitates replanting. Those that are grown for seeds, such as caraway, coriander and dill, are allowed to ripen, but are picked before the seeds begin to fall. They are dried in-doors and the seeds threshed out for winter use. Bailey, in his “Vegetable Gardening,” has a list divided as follows:—

ANNUALS (OR GROWN AS SUCH).

Anise Sweet basil Summer savory Coriander Caraway (biennial) Clary (biennial) Dill (biennial) Sweet marjoram (biennial or perennial)

PERENNIAL.

Sage Lavender Peppermint Spearmint Hyssop Marjoram Balm Catnip Pennyroyal Rosemary Horehound Fennel Lovage Winter savory Tansy Wormwood Costmary Tarragon.

CHAPTER XXIV.

PERENNIAL CROPS.

The vegetables in this group have little in common except their cultural wants or requirements, but these are so different from the needs of annuals that it is convenient to group them together. Because they occupy their places more or less permanently, it is necessary to choose a spot that will not interfere with the regular plowing and tilling of the farm or garden. Perennials need tillage in the spring and fall and are fertilized by top dressings, at both seasons.

ASPARAGUS.

The chief of the perennials is asparagus, which requires a deep, rich, moist, cool soil, with a warm exposure. It originally grew in rotten sea-weed on the shores and is a gross feeder, so the soil cannot be too rich. Sub-soiling to the depth of two feet is good for asparagus. It used to be thought that a layer of salt at the roots made a good fertilizer, but salt is no longer used in that way. It is, however, used to keep down weeds in the asparagus bed, especially the German salt known as kainit. This kills out weeds, saves cultivation, and adds potash to the soil.

If the land you have is hard and coarse, you should prepare it by planting it with some crop that needs a great deal of tillage, such as potatoes, for two seasons before you plant asparagus. During this time you should apply all the manure the land will carry, because, as the bed will last for twenty years, in the Northern States, you will have no other opportunity to put the soil in proper condition. Don’t be afraid of making the soil too rich. Asparagus can take all you can give, and will repay your generosity.

As you make your asparagus plantation practically for a lifetime, you must exercise care and judgment in choosing the site. In a family garden a long row, say 75 to 100 feet, if you have the space, at the rear of the garden, is a good place. This not only puts it out of the way of other crops, but it also gives you a good background in summer and fall, for the herbage of asparagus is ornamental. Asparagus used to be planted in beds, but under new methods of farming, this plan has been abandoned. Rows are more satisfactory. When grown as a field crop this allows of horse-tool tillage and saves much labor.

Asparagus roots are wanderers and reach out for food in every direction, even more horizontally than perpendicularly, which is why it is unwise to have rows closer together than four feet. Seedsmen sell asparagus plants, but it is usually better to grow your own plants, although they take so long to mature. Seeds may be soaked in warm water for a day before planting and are then sown in drills and covered about an inch deep. The plants should be thinned to stand three or four inches apart in the row.

Give frequent tillage throughout the entire season, and in the spring following they will be ready to plant in their permanent place. Here they are set deep, in a furrow or trench, say six to ten inches, so that the young crown of the plant is covered two or three inches deep with loose earth or good fine compost. As the plants grow the trench is gradually filled. If filled at first, the young plants might not be strong enough to push their way up.

You will see from this that the asparagus plot must be deeply sub-soiled, for if you do not have the land properly prepared at the first, you will never have good results. Besides, unless the soil is rich in humus, asparagus cannot thrive at all, for it requires a moist soil at the roots all the season.

When you have planted your yearling seedlings you must give them another year before you do any cutting. A few stray shoots may be picked off, but it is advisable to wait until the plants are in their third year before cutting. To cut earlier may permanently injure your crop. It is also possible to injure it by continuing it too late each season, although every stalk should be removed even if it be too poor for use. The crop should be cut clean, and all cutting should be over before July 4th, in the middle Atlantic States. After that the tops do the growing and the more they flourish the better your asparagus will yield next year, for it is from the foliage which springs up that the roots and crown secure energy for the next season’s work.

The tops should be mowed late in the fall, and generally speaking it is better to burn them than to allow them to rot on the bed as some growers do, because when the asparagus berries are plentiful you are apt to have trouble next season with seedlings; and even when this is not so, it interferes with the fall tillage which is so necessary.

Just as the young plants were covered with earth and manure the first year and thoroughly tilled in the spring, so must spring and fall tillage be carried on every year. The manure put on the plants in the fall, serves not only as a winter protection, but if not too coarse, may be cultivated under in the spring and afford that much more fertilizer to feed the crop. If it is too coarse for that, rake it off, cultivate thoroughly and then cover again with litter or manure, to afford nourishment and to preserve the moisture of the soil as well as to protect the young shoots in case of late frosts.

The whole value of asparagus lies in its tenderness and succulence, and the large shoots are most apt to have these qualities. The plant cannot grow large shoots unless it has plenty of food. Only rich soil and good tillage can supply the food needed.

Usually asparagus is cut off three or four inches below the surface with a long sharp knife, but one noted asparagus grower objects to this practice for two reasons. First, it increases the temptation to cut too low so as to get the stalks of uniform length as the market requires, whether or not of uniform quality; and second, it tends to waste and to the injury of the plants. He would substitute for this practice, careful hand-picking or breaking. The gatherer takes two rows at a time and breaks off the shoots just beneath the ground at the lowest point where the shoot will break with a clean snap.

When set at the proper distance of three by four feet apart, it requires 3630 plants to the acre, and 1 pound of seed should furnish that many plants. But seedlings vary so much, that some growers recommend sowing from four to five pounds of seed to every acre, so that only the best need be kept. A good yield is about 400 dozen bunches to the acre. Asparagus is always sold in bunches, the stalks of uniform size and length, and tied near the tops and butts either with bark or string; though many growers are now using rubber bands as being better for the stalks and a saving of time for the gardener.

Asparagus is usually sold green in this country, although if artificially blanched it is just as tender. When asparagus is grown for blanching it should be planted deeper than ordinarily. It is hilled up with a furrow plow just as celery is hilled up, and blanches as it grows. Blanched asparagus is in higher favor in Europe than here.

Asparagus is a native of Europe and Asia, and has been cultivated for more than two thousand years. It belongs to the lily family and several of its very near relations are cultivated in greenhouses for their graceful foliage.

The asparagus beetle is the worst enemy and must be steadily fought. In young beds, apply fresh air-slaked lime as soon as the larvae appear. It should be put on while the plants are still damp with dew, and only the greatest thoroughness can accomplish anything. Destroy all volunteer shoots. As the beds are cut, leave some small trap-shoots upon which the beetles will gather; cut these twice a week and destroy. In hot weather brush the insects off and they will bake on the soil in the sun.

It is so risky to use poisons on asparagus that is to be eaten, that Paris green may be used only in very rare instances; then the mixture consists of one pound of the poison to fifty pounds of air-slaked lime. Two applications are made, about a week apart.

Some gardeners turn a hen with chickens, or a number of young chickens, into the asparagus field as soon as the crop is cut. This is one of the best ways of keeping down the beetles, and the scratching of the fowls cultivates the crop. This will lessen your own work and increase the value of your chickens to you.

Rust is the chief disease, and for this there is no sovereign remedy. Every effort should be made to secure only vigorous plants, and in very dry weather irrigation should be practiced, if possible. Early in the autumn, cut, carefully gather together and burn, all affected stalks, and all asparagus brush whether garden or wild. Read Massachusetts Bulletin 61; Iowa Bulletin 53; Farmer's Bulletin 61, p. 30.

RHUBARB.

Of all the perennial garden plants rhubarb is the easiest to grow, and the most inexperienced may be sure of success. It is very hardy and the roots remain in the garden all winter, even in climates where the frost is heavy and the cold quite severe. But in spite of its hardiness and willingness to flourish under ordinary conditions, rhubarb responds quickly to good care and gives such enormously increased returns that it pays to attend to it.

Rhubarb likes a deep, rich soil, thoroughly cultivated and fertilized before the plants are set out. It is usually more satisfactory to propagate by roots than by seed, although some growers prefer to raise their plants from seed. Like asparagus, rhubarb will last twenty years, if given a good start and if the roots are occasionally separated. All this time it will yield large, tender, juicy stalks if the soil be in good condition, and if a little tillage is given to the plant in fall and spring.

Set out the plants in rows where the soil has been fertilized, is deep and in good tilth. The best strains of rhubarb will not produce good stalks if the land be hard or the subsoil high and hard. The rows should be four feet apart to allow of horse tillage. The plants may be from three to four feet apart in the row. During the growing season they require the same sort of surface tillage that you would give to corn or potatoes. If you are making the most of your rhubarb bed, you will give it quite a heavy coat of manure in the fall, to act as mulch to keep the soil from freezing too deep, and also to preserve its texture. During the storms of winter, the manure leaches away somewhat and fertilizes the roots, so that they are prepared to make an early growth in the spring.

The season for selling is short, as early in the summer the demand for rhubarb gives place to strawberries and other small fruits. It is the grower who has it early in the market who reaps profit from rhubarb.

By means of the New Rhubarb Culture, rhubarb may now be forced for market out of season, and then it brings the best prices of all. Roots are left in the garden until they have been frozen and are then transplanted to specially prepared beds and forced for the Christmas trade. These beds may be in the open field if one has a system of heating by steam forced through trenches, or they may be in specially constructed forcing houses; or, simplest of all, they may be in the house cellar, even though the floor be of concrete.

Rhubarb requires but little moisture and when it is being forced, it need not go deep to find its food, if the soil it has is rich enough. Three inches of earth will give it all the hold it needs, and if the light is completely excluded, the growth will all go to stalk.

If you have a cellar bed, screen it off from the rest of the cellar so that no light can reach it; a small kerosene-oil lamp with a chimney that has been thoroughly smoke-blackened, will give all the heat necessary to start growth. The stalks begin to shoot up looking for light and will do almost nothing in the way of leaf-growth because of its lack. In this way the whole energy of the plant is diverted into profit-making stalks.[9] The roots that have been forced for the Christmas market cannot be used again the following season. They need a season's rest. (Read J. E. Morse's "New Rhubarb Culture.")

But this absence of leaf, which is so desirable in forced rhubarb, would be injurious to the garden rhubarb. In out-of-door growth, the vigor and fruitfulness of the plants in any growing season, are largely determined by the spread of leaves in the preceding season. For this reason, after the cutting season is over, the plants are encouraged to develop leaves; the smaller and weaker ones being cut off that the large ones may grow still larger, but all seed stalks should be cut, so as to preserve the vigor for next season's growth of stalks.

When ready for market, rhubarb is tied in bunches of two to five stalks and an acre will produce about 3000 dozen bunches. That is a pretty good return when it requires only about a pound of seed to sow an acre in the first place.

Rhubarb is native to eastern Asia and has no serious insect enemies or diseases.

DOCKS AND SORRELS.

Those who are fond of very early greens will be glad to know of the garden varieties of docks and sorrels which come earlier than any other pot-herbs. They were originally imported from France where they are in general use.

The best varieties are the Spinage Dock and the Large Belleville, really a sorrel. The Spinage Dock is a week or ten days earlier than the Belleville, has larger, crisper, greener leaves and a less acid taste. Cornell Bulletin 61 says: "All these docks are hardy perennials, and are very acceptable plants to those who are fond of early greens. Some, at least, of the cultivated docks, can be procured of American seedsmen."

ARTICHOKE.

The Jerusalem artichoke, the variety best known in this country, and the French Globe or true artichoke, have little in common, yet both are used for food. The eatable part of the true artichoke is the flower-head, which should be cut before it has fully spread, else it will be woody. It is a strong-growing, upright, perennial, reaching a height of four or five feet, with large leaves. It is not always satisfactory to plant from seeds, as they cannot be guaranteed to reproduce truly. But when seed is sown it may be where the plants are to stand or in hot-beds.

The advantage of hot-bed sowing is that the plants may give heads the first year, while those planted in the garden require two seasons to produce eatable heads. The best means of propagation are the suckers which grow freely about the root crowns. Suckers are planted where the plants are to mature and give heads the second year.

Although the artichoke is perennial, it weakens after yielding two or three crops, so that it is well to replant part of the bed each year, thus keeping a succession of vigorous plants. In cold climates the heads are protected during the winter with a mulch of straw or litter. When boiled tender and served with Hollandaise sauce, made of melted butter and flour, the artichoke is a delicious vegetable, but it is comparatively little known in this country.

The Jerusalem artichoke is grown for its tubers, which are underground as in potatoes, and it needs much the same preparation and tillage as potatoes. It is usually fed to stock, especially pigs, but of late it is coming to be recognized as a good food for man, too. "If you will feed the pig, the pig will feed you," but we need not go through that troublesome process; for a varied vegetable diet alone is healthy for most persons—and much cheaper.

Artichokes are really more nourishing than potatoes, and the improved varieties may be used in place of potatoes. The plant is perfectly hardy, being native to the Northern States and Canada, and will take care of itself when once started, although it is better for having its roots divided, by digging them up. It will run wild, if wholly neglected, and become a troublesome weed, propagating itself indefinitely by means of its straggling, far-reaching, tuber-bearing roots. The only way to cure this damage is by thorough tillage, the first of which consists of fall plowing and the turning of pigs into the patch to root up the tubers.

The artichoke is more prolific than the potato, and will yield all the way from 250 bushels to 1000 bushels per acre with only ordinary care. For eating, the best variety is the Improved White French. The Jerusalem artichoke is not likely soon to supplant any other garden crop in this country, but it might well become a regular garden crop, as it will grow on land too poor for most other plants, requires little care, yields heavily, and is good food for man and stock.

SEA-KALE.

Sea-kale is one of the least known of the perennial garden crops, although where it is known it is well liked. It is a low, fleshy-stemmed plant whose shoots and young leaves are blanched and eaten as asparagus is. The plants may be grown from seed; in which case all but one main stem are to be cut off as soon as they appear; or it may be grown by division of roots. In either case, it is well not to cut from the plant until the second season. The shoots are blanched either by covering the crowns with fine, loose soil for a foot or even more, in the early spring, or by covering the crowns with a box and allowing the shoots to grow up in the dark.

After the young shoots have been picked off, the plants are allowed to grow as they will; for, like asparagus and rhubarb, the vigor, size and yield of the next season depend upon this season's growth of leaf and root. It flourishes best in deep, rich and rather moist soil. The plants should not be less than three feet apart each way, and they are much benefited by an autumn dressing of light manure or straw.

FOOTNOTES:

[9] NOTE.—You can get long stalks in the garden by putting a small cask, or half-barrel, with the ends knocked out, over the plant. The stalks will grow to the top and blanch some while growing.

CHAPTER XXV.

SPECIALTIES.

It is well to grow a variety of crops for your own experience and your own table. But for profit, it is best to specialize, because if you read up all you should know about several crops, you will have no time to raise them.

Specialization is the rule now in all lines of business, and as the farmer gets to be more and more a business man, he will adopt business methods, and push ahead. The big farm, partially cultivated, and covered with a great variety of crops which require as many varieties of cultivation to give good results, is a thing of the past, except where some individual farmer is too stupid to read the handwriting on the wall. It never paid as it ought, and it entailed tremendous labor. Now big areas are only cultivated where lots of help is employed, and diversity of crops can only be successfully practiced under the same conditions.

Today the custom of cultivating small areas is increasing, and where it is done for profit, the grower more and more tends to specialize. Secretary Critchfield, of the Pennsylvania State Department of Agriculture, said some years ago that "the greatest amount of money in farming was to be made in specialties," and that the country boy in deserting the farm was "running away from opportunity." This has since been proved true, and today it is possible for either girl or boy to make a good living from even a small piece of land, if she or he will only give intelligent attention to the matter.

It requires labor, to succeed in farming, but so does any other calling, if one wishes to master it, and there is no calling that assures so much independence. People must eat, and the food must be grown for them, whether the times be hard or easy; and even should times be so hard that you can't sell your product freely, you can eat it freely, and you can not be sure of food and room if you are in a shop or in an office. The American farmer and gardener are the nearest to free workers in the world.

The most unlikely things may bring profits when grown as specialties. One man who has a farm in Lewisburg, Pa., is making a good living from raising chestnuts. His profits on their sales average several thousand dollars a year. He made a study of chestnut growing, until he knows a lot about it, and has grafted young trees with Japanese and Paragon chestnuts, thus increasing the quantity and improving the quality of his crop. He has done so well at this, that the Pennsylvania State Agricultural Department has issued a bulletin setting forth in detail Mr. Sober's method of chestnut culture. If you are interested you can get the bulletin by writing to Harrisburg, Pa., for it.

Mushrooms offer a pretty good opportunity to make money, if careful attention is given to detail, but they are still mighty uncertain wild things. It is impossible to give the details of cultivation of specialties within the limits of a book, but if you apply to the Department of Agriculture you can get much information.

The Department publishes three bulletins which cover the subject:—Cultivation of Mushrooms, No. 204; Food Use of Mushrooms, No. 279; and Growing Mushrooms for Home Use, No. a233. Some mushroom farmers near Wawa, Delaware, according to a report in the Philadelphia _North American_, are clearing from $2000 to $3000 a year from four or five acres.

Asparagus, celery and many other garden crops lend themselves readily to special cultivation and yield a good profit. So also do onions and even potatoes. One man at least claimed to have produced as many as 3000 bushels of potatoes from one acre in one year. He published a pamphlet setting out his method, but it is now out of print. So big a yield entails too much labor for the average grower, but a third of that number of bushels would yield a handsome income. But, ordinarily, it does not pay to raise potatoes in a small garden.

Mr. C. E. Ford, who lived in Cherokee County, northeastern Texas, tells of raising two such incredible crops of potatoes annually from his land, and his method seems simple as set out by Finney Sprague of Chicago in a small book which was published in 1905.

Mr. Ford had a sandy soil with a clay subsoil three feet below the surface, which he says he ridged up into dykes; then he used immense quantities of cotton-seed for fertilizer as well as liquid manure. One of the important features was his rich fertilizing, and though it sounds expensive when compared with the ordinary quantities of manure used, it is really cheap if anything like such results can be had. Commercial fertilizers suited to potato growing may be used in place of cotton-seed, and the grower claims that the method may be followed from Canada to Texas successfully, securing at least two crops of potatoes a season.

According to his method, the seed used must be of uniform size, running about 80 potatoes to the bushel, and averaging about ¾ of a pound each in weight, smooth and bright. Half of such a potato is used to each hill, or if the potatoes weigh only six ounces, a whole potato is allowed for each hill. For intensive cultivation the potato must be sprouted before planting and for this purpose you need a “sprouting room.” Any room, say 10 × 12 × 7 feet, if warm, dry, double-walled and lighted will serve the purpose; or you can construct such a house with sawdust filling between the double walls and double ceiling, having two windows, and a roof over all: an old ice house would do.

Lay two rows of two by four inch scantling on the dry earth floor, near the sides and across the end of the room opposite the door, and place on them a double row of barrels, each filled about three-quarters full of potatoes, or about three bushels to each barrel. When these have been filled this way, lay scantling across the barrels so as to accommodate other tiers of barrels, until you have about 50 barrels in the room. No earth or water must be used in the barrels; just the plain potatoes. In the centre of the room place your heating apparatus, which may be a small “bake oven” in which one barrel of charcoal will supply all the necessary heat during the four to six weeks of sprouting; or a small stove burning coal or wood so that a _low_ fire may be kept day and night to maintain a temperature of 80° to 90° Fahr., or, even a small oil-stove may be used.

[Illustration: A SHELTERED SUBURBAN GARDEN PATCH.]

Here the potatoes will sprout and send out rootlets having thousands of small tubers upon them, from the size of a bird’s eye to that of a marble. If you start this sprouting four to six weeks earlier than the ordinary time of planting, you will get your crop just that much ahead of the regular season.

Only the best of seed potatoes are used, and Early Rose is the favorite variety, but Mr. Ford says, “that sort is best which is known to grow best in the section of the country where you live.” In the ordinary culture of potatoes, it requires about 30 bushels of seed to the acre, and 300 is a large yield. By Mr. Ford’s method, it takes 140 to 150 bushels to the acre, and the returns are claimed to be 3000 (three thousand) and more bushels. That is, using four or five times as much seed, you get 10 or more times as large a yield.

If you intend to experiment on this way of planting an acre, let it be as nearly square as possible, which will give you about 70 rows, each about 209 feet long. Ideal potato land is so light that the soil offers little resistance to the growing of the tuber; so thoroughly tilled and filled with humus as to be quite moist without being wet, and so richly fertilized as to contain a very large quantity of plant food.

Starting on the left side of your acre, with a narrow plow, turn a furrow to the left the whole away across; then turn and go back, turning a furrow to the left as you go, far enough from the first to leave a ridge about four to six inches across between them; then go round the whole thing once more, inclining the plow to the left all the way, and guiding it so as to leave the ridge. This will use up the three feet allowed to each row. Continue across the field after the same fashion, seeing that each row is three feet from each other row, and that the unplowed ridges or “balks,” as they are called, are also three feet apart.

Mark the places for the hills on the top of those ridges, placing each hill 18 inches from each other hill. The plowed earth between the ridges is what is turned back to cover seed, to make the hills and to cultivate with afterwards, while the wide ridge affords a good surface for depositing the seed and for the expansion and growth of the tubers.

Two or three days before you intend to plant, harden off your potato sprouts by putting out the fire and opening door and windows until the temperature is as nearly as possible that of the outside. Then, all being ready, have the barrels carried to the potato field, on a hand-barrow by two men, not wheeled on a wheel-barrow. Knock off the hoops and staves, so that the sprouted mother potatoes may be freely but carefully handled.

Separate the mother potatoes with a wooden paddle, as it will do less injury than an iron one. The loss need not be more than 10%. Lift out one mother potato, being careful not to break the sprouts or rootlets. If the potato be a 12-ounce one, cut it in halves lengthwise, not crosswise, so that each portion shall have as many as 15 little tubers on it, so far as you can estimate quickly by counting with the eye. Lay each portion where the hill is to be, on opposite sides of the ridge, with the roots spread down the sides of the ridge, thus making a double hill, planted with anywhere from 40 to 60 little tubers, ready to resume growth at once.

Never plant less than 15 tubers to each hill, and if the half mother has less than that number, add a portion of another mother until you have that many. Only in this way can you estimate how many bushels you will have. If each half has more than 15 tubers plant them all. If you use 6-ounce potatoes for seed, plant the whole mother in each hill. Cover the seed with two furrows of the turning plow.

If the ground has been properly prepared, cultivated and irrigated during drought, practically every one of these tubers will grow to a uniform-sized potato, and 75 to 80 of them will make a bushel. Thus 70 rows with 140 double hills to each row, every hill containing 25 matured potatoes will, he says, give 245,000 potatoes, which at 80 to the bushel means 3060 bushels; if 30 potatoes to each hill, there will be 294,000 or 3675 bushels.

If a second crop is desired, have the mother potatoes ready when the first crop has been marketed and the ground once more thoroughly fertilized. Of course, whether it is first or second crop, the best tillage is none too good. Anything that stops the growth of the tuber at any stage, is fatal to your hopes of a uniform-sized crop, so be sure that there is no danger from drought.

In the case of the second crop, do not allow the potatoes to remain in the ground until touched by frost. This means pretty close watching, as the ripening of the potato is largely a matter of the last three weeks of growth, so they must not be dug too early, any more than too late.

Although this method will give far larger results than any other yet reported, it may not be practicable, nor may it give such phenomenal crops always; still, it is not the only case of enormous crops. As far back as 1828 crops from 900 to 1340 bushels per acre had been grown in England, and in 1884 the Editor of the _Rural New Yorker_ reported a yield of 1391½ bushels from an acre on the paper's experimental farm. In the light of such figures, the average of 100 bushels looks too mean to be considered. Why not grow more?

Potatoes cease to grow when they become dry, so the grower must see that the land is irrigated, and liquid manure is the best material, although plain water will do, if the soil is richly fertilized. Many growers now plant on flat land and hill up only to counteract too much moisture.

Then there are profits in small fruits if intensively cultivated. Strawberries will always find a market if they are large, ripe, sweet and clean. Anybody can grow small, sour ones, and they will sell, but there is no profit in the price. The market is never so glutted that fine, large fruit will not bring a fancy price. Be sure in picking, to have three baskets on a board, and have the picker assort the berries as picked. Usually, this will about double the price that you can get. A good yield is 6000 quarts per acre, but they have been known to yield all the way from 21,000 to 35,000 quarts per acre. (See "A Little Land and a Living," pp. 141-143.)

The good price is for the garden product that is better than its kind, and specializing on one thing helps to make you grow the best of that thing. You naturally try to find out all you can about it, and if there is an improved method, or somebody has grown a larger crop than you, you are going to know how he did it. Grow your family vegetables on a portion of your plot, but if there is room at all, save the rest for some specialty.

If you cannot grow crops at all, perhaps you can specialize on raising animals. You have a considerable variety to choose from, because, as I have shown in "A Little Land and a Living," and also in "Three Acres and Liberty," there is a market for everything, from bees and poultry to fish and silver foxes. (The foxes were sneered at, first off, but the Department of Agriculture has just published a bulletin on breeding foxes.)

CHAPTER XXVI.

WATCHING AND SPRAYING.

Now suppose you have prepared your soil properly, and planted your seed carefully; that your transplanting has been done, and your crops are growing; do you think your work is done, and you have only to wait for sun and rain to do the rest? If that is your idea, you are not cut out for a farmer. Get out of the business as soon as you can. There are no “soft snaps” in farming or gardening, on either a large or a small scale. But the man in love with his job, no matter what it is, is not looking for soft snaps, nor does he find his work hard. There is a reward in tilling the soil and in watching “the green things growing,” as Riley has it, that is not excelled by the rewards of any other calling.

It is absolutely necessary that you should watch your growing crops, for only in that way can you keep in touch with their needs. The parent who neglects to watch his children and to look out for their physical needs, generally has doctors’ bills and anxiety. A little watchfulness would have revealed the first stages of decay in the teeth; the early signs of adenoid growths; the symptoms of eye-strain, or the irritable state of the digestive organs, and the trouble could have been stayed. To be sure, the ounce of prevention costs something, but not nearly so much as the pound of cure. It is a question of business foresight, as well as parental affection, to watch the child, and the crop, and forestall disease.

Crops need careful watching, and to forestall most diseases there is nothing better than spraying. Once upon a time the man who sprayed his crops was a rarity, and his neighbors were not sure that he had not taken leave of his senses, but now the man who does not use the spray, is the notable exception—a monument of foolishness.

If you take the pains to find out what your soil will grow, you will know what insects and diseases are likely to attack your crops, and you can plan your campaign against them with intelligence.

Begin at the beginning, which is in the winter. First find out what spraying mixtures are best for dealing with the pests you are to meet. This can be done by writing the Department of Agriculture or by the study of books. Then study agricultural papers and Department bulletins as to the best spraying machines or nozzles on the market, and buy what you need.

Where any doubt about the quality of seed exists, it is often a wise precaution to spray it before planting, but you must spray your growing crop on the very first sign of insects or diseases. Remember that bugs do not like poison, and will not go where it is; therefore, you must take it to them in good quantities. Partial spraying is little better than none. Do the job thoroughly, when you start in to do it at all. See that the whole plant from root to top is thoroughly saturated—stem, branches and leaves. One spot untouched by the spray makes a sure refuge for the bug. Don’t sympathize with his homeless condition at the expense of your crop.

Bordeaux mixture is a cure for almost every variety of plant disease. It consists of sulphate of copper (blue vitriol) and lime, diluted with water. The principal use of the lime is to make the mixture stick to the plant and to render the copper sulphate less caustic, and one thorough spraying, if rain does not come for a day or two, will cling to the plant for a couple of weeks. This mixture can be safely used even before there is any sign of disease, and it then acts as a preventive. But where disease is severe, apply it every few days, because the new leaves and shoots offer so many breeding places for the disease spores.

To make 12 gallons of Bordeaux, use one pound of copper sulphate and one pound stone lime. Be sure to use wooden vessels, as vitriol eats tin; an oil barrel, sawed in halves, makes good tubs for dissolving the vitriol and slaking the lime. Put one to one and a half gallons of water in the tub and hang the vitriol over night in a piece of burlap, which just touches the water. Slake the lime in the other tub by adding water as fast as the lime takes it up, and no faster. When both are properly dissolved, fill the spray barrel about one-eighth full of water and add the solution of vitriol. Add enough water to the lime barrel to make 2½ or 4 gallons and then strain the slaked lime into the spray barrel through a wire fly-screen or two thicknesses of potato burlap. Fill the barrel with water enough to make 12 gallons of mixture, and stir thoroughly for some minutes. If your spray has an “agitator” attachment, you need not trouble further, but if not, you must stir the mixture thoroughly every few minutes while spraying.

Bordeaux mixture should be made fresh for each spraying, but the vitriol and lime may be prepared ahead in large quantities, if they are not mixed, and are kept covered to prevent evaporation. Thus forty pounds of vitriol may be dissolved in 40 gallons of water, and forty pounds of lime slaked in 40 gallons of water. Four gallons of each will make a basis for 50 gallons of Bordeaux mixture.

The only disadvantage to Bordeaux mixture is that it discolors the plant, it being a “blue whitewash”; and those who object to the discoloration often use the ammoniacal carbonate of copper, rather than the sulphate. But this is not so sure a remedy, neither does it stick so well. It is made by dissolving an ounce of carbonate of copper in a pint of water and adding it to a quart of ammonia. If the ammonia is strong, use only enough to thoroughly dissolve the copper, otherwise it will injure the plants. Cork the mixture tightly and when wanted for use, add from 8 to about 20 gallons of water to each ounce of the copper. This is used principally on fruit that is nearly grown, or upon purely ornamental plants, to avoid discoloration.

Bordeaux cannot cure internal diseases of the plants. These may be caused by insect borers at the roots, or by some incurable bacterial trouble, and in this case there is nothing you can do but root up the affected plants and destroy them, and then study out how you can prevent its happening again.

Sprays for insects usually consist of some form of arsenic or of kerosene emulsion, and occasionally whale-oil soap is used. The most common form of arsenical poison is Paris green, of which about 2000 tons are used annually in this country; this is mixed in the proportion of one-half pound of Paris green to 100 to 150 gallons of water and one-half pound of fresh burnt lime.

However, where the insects are very bad, as potato bugs often are, the same amounts of Paris green and lime may be mixed with only 50 gallons of water. Paris green is too caustic to apply stronger than that, except in very rare, specified cases. The Paris green should be mixed with a little water till it is smooth, before it is added to the larger quantity of water. Sometimes it can be sprinkled on, but the only sure results are secured by using a spray, either hand or power.

Sometimes Paris green is added to the Bordeaux mixture, and the crops sprayed for insects and diseases at the same time. When this is done, you regard the Bordeaux as water, and add the Paris green in the same proportion as you would add it to water. In this case you need not add the lime, because the lime in the mixture is sufficient. London purple is sometimes used in place of Paris green for the same purposes, and in exactly the same proportion and ways, but it is not so easy to know how strong it is as with Paris green, and it is being used less and less each year.

Another preparation is arsenite of soda, which is made of white arsenic, two pounds; carbonate of soda (washing soda) eight pounds; water two gallons. These must be boiled in an iron kettle, which should not be used for any other purpose, for about fifteen minutes, or until the arsenic dissolves. Some water will evaporate during boiling, so, before bottling, add enough to make the full two gallons. This will keep a long time if tightly corked. To make a spraying solution add one-half pint to 25 gallons of water. The quantity given is, therefore, enough to make 8 barrels of 50 gallons each. Unless mixed with Bordeaux, add two pounds of slaked stone lime to each barrel. Be sure to mark your bottle of solution plainly, “POISON.”

Arsenate of lead clings to foliage better than any other arsenical poison, and since it does not burn foliage it can be used alone, in the proportion of from one to five pounds to 50 gallons of water. It was first used in 1892 against the gypsy-moth and is annually growing in favor.

All insects which feed on the outside of plants are divided into two classes—the chewing or biting insects like beetles and larvae (worms), and the sucking insects, which include the various scales, plant lice, and squash bug. The chewing and biting kinds are killed with the Paris green solution, but the sucking sort need kerosene and preparations which kill by contact.

There are many ways of making the standard kerosene and soap emulsion, but Bailey recommends the following method as the best:—Put one-half pound of hard soap into a gallon of boiling soft water; as soon as the soap is dissolved, add two gallons of kerosene or coal-oil. This mixture should be of a milk-like consistency, which can only be secured by running it through a pump vigorously for fifteen minutes or more. For use on plants or trees, it is diluted with ten to fifteen times its bulk of water. It can be used stronger than that on trees in the winter. It is sure death to scales and plant lice if applied early enough; this is another proof of the value of watching your growing crops.

Within a few years, pumps have been invented which will perfectly blend water and kerosene without the addition of soap, and this is by far the better remedy. Without soap, the proportion of kerosene can be increased to even one-fourth the quantity of water, without injury to the plants, if the application is made while the sun is shining. This emulsion is fatal even to the dreaded San José scale. As experiments are constantly going on along this line, the up-to-date farmer or gardener will keep in touch with the latest discoveries.

Whale-oil soap, one pound of soap to four or five gallons of water, used to be a popular remedy, but it is rapidly giving place to kerosene emulsions, which are more easily prepared and less offensive. Tobacco dust will drive away cucumber and melon

beetles, if liberally applied, and will lessen the ravages of the flea-beetle. But Bordeaux mixture well applied will do the same.

For treating cabbages or other crops late in the season, white hellebore is often substituted for Paris green, which is a deadly poison. It may be applied dry, alone or mixed with half as much flour; or in solution, one ounce to three gallons of water.

Spraying enormously increases the yield of any crop, and indeed sometimes makes all the difference between good crops and no crops. So long as insects and diseases exist, any patch in any part of the country is liable to attack. Because you have escaped so far is not to say that you always will escape, so be ready for emergencies. Timeliness and thoroughness are two essentials, and these can only be secured by combining watching with spraying. It pays. Six years of potato spraying at Geneva, N. Y., increased the yield 122 bushels to the acre when sprayed five times during the season. Where only three sprayings were given, the increase was 93.6 bushels per acre.

You may be discouraged by these infinite details of care and management: but if you have not the time or the inclination to attend to them, that is not a reason for neglecting the study of Intensive Farming.

It is a reason for not undertaking a greater variety of crops than you can master; a succession of well-chosen plants will fill all the time you choose to give. I am showing how the best results can be obtained, but the most ordinary farmer will find his returns vastly increased by applying as much of these methods as he can manage.

For instance, at the South, the uneducated negro finds that his cotton crop is often increased, from half a bale per acre to two bales on each acre, by merely putting in a clover crop before the cotton.

Apply what you can learn, as far as you can: the power to learn more and to use it will come by use.

CHAPTER XXVII.

FERTILIZERS.

A fertilizer is something added to the soil in order to increase the crop yield. Chemical fertilizers are very valuable when very intelligently used—but look out for them. People seem to have a great love for all sorts of complicated ways of doing things that nature will do naturally, and any one who proposes unnatural processes like vaccination, or like medicining the soil, should be required to make a very strong case for it.

Besides, you remember the story about the darkey who has been playing poker. He said: “Tell you, boys, I dun los’ a heap o’ money las’ night.”

“How much, Mose?”

“A hunnerd and eight-seben dollahs an’ fohteen cents.”

“Golly! dat wuz a heap o’ money.”

“Yas, siree, and de wust ob it wuz, de fohteen cents wuz cash.”

So it is with the boughten fertilizers. Sooner or later they have to be paid for in cash. The outgo is certain, but the income not so certain. Therefore, be sure you know just what you are doing, and why, before you buy. Of course there are times when commercial fertilizers are absolutely necessary if only to start the growth, but we should be sure what we are getting.

When we try to find out something about fertilizers, we get such technical and complicated explanations about phosphates and nitrates and other “ates,” that the ordinary amateur or beginner just takes some one’s advice; while the professionals mostly stick to what they have been doing. But the subject is clear enough if it is clearly stated.

Nitrogen and potash are about the best elements in artificial fertilizers and perhaps the hardest to retain. We have learned that nitrogen can be best and cheapest added to the soil by means of certain cover crops, or crops sown only to be turned back into the ground as green manure. It is also present in large quantities in stable manure, if it has not leached away before being put on the field. But this book could scarcely tell you all about the best ways of handling manure to get the best returns. The Government, however, has done this, in Bulletin 192, and you cannot do better than send for it and study it carefully. You will learn from it the immense importance of taking proper care of the manure you have, and how to get the best possible results from its use. Also,

what sorts of manure are best for what special purposes.

If the manure is carefully handled, that which is obtained from stock fed for soiling purposes—that is, especially to provide manure—is the best. It contains almost all the elements that the growing crops took from the soil.

One well-fed dairy cow will produce 12¾ tons of manure in one year, says Prof. E. B. Vorhees, and this manure will contain about 117 pounds of nitrogen, 77 pounds of phosphoric acid, and 89 pounds of potash. This much stable manure, if all the constituents are saved by housing and careful handling, will grow about 70 bushels of wheat and the accompanying straw. As all this nitrogen, phosphoric acid and potash have been drawn from the soil first in the crops fed to the cow, the only way to keep up the fertility of the soil is to return them to it. In the form of commercial fertilizers these would cost more than $30, or 20 cents per pound for nitrogen and 4½ cents per pound for potash and phosphoric acid.

So if you keep one cow and feed her well, she will return to you almost her value in manure each year, to say nothing of the milk and butter your family can have. The family horse, as well as the cow, will give you valuable returns in manure, if you know enough or care enough, to preserve it properly.

When immediate spreading on the fields is not possible, the manure, both liquid and solid, should be kept in a tight pit, or under cover. If too much litter has not been used, the liquid part will prevent loss from too rapid fermentation. But if there is litter enough to make the manure very dry, some water should be added from time to time to let fermentation go on without loss. Manure thus cared for will be ready for use on the land at any time that it is needed, and will contain practically all the necessary fertilizing properties.

A German proverb says: “The manure pile is the farmer’s bank.” All farmers these days know the value of good manures, which accounts for their buying so much commercial fertilizer, but some day they will know the value of saving the whole of the stable and barnyard manures, so as to avoid the cost of commercial fertilizers. Then there will be less of that unscientific talk of “depleted soils,” and no grumbling about “decreased yields.”

Sea-weeds, ashes, “mucks” and bones are all valuable as manures if handled properly. The Maine Agricultural Experiment Station, at Orono, Me., has published a bulletin, No. 74, on the manurial values of these, which will be sent upon application, and is well worth the reading.

The farmer should remember that commercial fertilizers are only to be used to supplement manure, not to take its place, and that when he buys any, it must be the best. He cannot afford anything else. The man who says, “I know my land needs potash, but I cannot afford to buy it,” is making a mistake. Suppose he should say “I know my children need bread, but I cannot afford to buy flour!” His neighbors would think he had gone crazy.

It is just as foolish to deny his land what it needs. He should get whatever it needs; for if a soil needs any certain ingredient, whether potash, phosphoric acid or nitrogen, it is cheap at a high price, while anything else is dear at a low price. Your soil must be fed as surely as your children must. You can get credit at the store or at the bank to buy fertilizer, when you could not get it to buy an automobile.

Potash is really one of the cheapest fertilizer elements on the market, but farmers get the idea that it is high because it is present in large quantities in all high-grade fertilizers, and almost absent from cheap grades. Just as a man’s wages cannot be estimated by the number of dollars he gets each week, but rather by the amount of the necessities of life that he can buy in return for the number of hours he has worked; so the price of fertilizer must be judged by the amount of plant food it contains, rather than by the money cost per ton. That is what makes high-grade fertilizer really cheaper than the low grades which cost less money.

For example, take the most popular of the $25 a ton fertilizer, “2-8-2.” This contains 12 per cent. of plant food, or 240 pounds to the ton, made up as follows: two per cent. nitrogen, eight per cent. phosphoric acid, and two per cent. of potash. This brings the cost of this cheap fertilizer to 10½ cents per pound of plant food to the ton. Now if the farmer bought a ton of plain muriate of potash, it would cost him $50 per ton, but he would get 50 per cent. of plant food, thus making the actual cost only five cents per pound of plant food, less than half the plant food price of “2-8-2.”

Few farmers want to buy the potash separately, and they complain that the manufacturer charges high for it in fertilizer where it is present in large quantities. But a little investigation will prove that this is not so. Take for example, the “2-8-10” grade which sells generally for $30 per ton. Here you have 20 per cent., or 400 pounds, of plant food to the ton. That brings the cost of plant food per pound to 7½ cents instead of 10½ cents as in the cheap grade. The manufacturer has added $8.00 worth of potash to the mixture

and has taken out some of the worthless filler, so that the extra cost in money to you is only $5.00.

The increase in yield more than offsets that extra cost. There are still other potash fertilizers that contain no nitrogen, the lower grades selling for about $16 per ton, and the higher grades for $20 per ton. The plant food in the lower grade costs 6■ cents per pound and in the high grade only a tiny fraction over 5½ cents per pound. If you are spending your money for commercial fertilizers, you will find that the best is the cheapest. No matter what the mixture, if you figure it out, you will find that the high grade costs less per pound for plant food than the low grade. And it is plant food you are after, not worthless filler.

The New York Experiment Station in one of its bulletins offers the following comment on this point: “The high-grade goods sell on an average nearer to their actual plant-food value than do the low-grade goods. In general, the higher the grade of the goods, the lower the cost of each pound of plant food.”

Before you raise any crop you must know your soil, not by chemical analysis which is interesting and often helpful, but by finding out what it will grow by nature and what is the easiest way that nature can be helped; and the quicker you can find out these things the better for your prospects. The simplest and quickest method of finding out what fertilizers your soil needs to grow your crops, is by using the paraffin basket. This is a very pretty experiment and one in which you can readily interest the children so that they may get their knowledge early.

The requirements are galvanized wire netting of one-eighth inch mesh; paraffin, which can be bought cheaply at any druggist’s; and a pair of scales which will weigh accurately to one-fourth of an ounce.

Cut your netting into strips 10 inches long and 3½ inches wide; fasten the ends of strips together by hooking the end wires into the mesh or with small rivets. Then cut the wire at the bottom of the cylinder so as to make lugs about a half inch deep and bend the cut pieces under to form a partial bottom. Cut a circular piece of netting that will fit inside and drop it in, thus completing the bottom of the basket. Melt the paraffin, and while hot dip the top of the basket into it for about one inch. Draw it out, that it may cool, and dip again until a solid rim of paraffin is formed. Number each basket, as it is easier thus to keep a record of it. Place them on a tray, or in a shallow box, for greater ease in handling.

Gather the soil in small quantities from different parts of your field or garden and mix it together. If you took it from one spot it would not be representative, any more than a Congress elected entirely from one section of the country could rightly be called a House of Representatives for the American people. Divide this whole amount of soil into equal parts, having one more part than you have fertilizers to test, because you should have one basket of untreated soil to act as a check to judge results by. Eleven sorts are usually tested, which makes it necessary for you to make twelve baskets altogether.

1. Untreated soil.

2. Soil with dry manure, at the rate of five tons per acre.

3. Soil with lime, one ton per acre.

4. Soil with nitrate of soda, 200 pounds per acre.

5. Soil with sulphate of potash, 200 pounds per acre.

6. Soil with acid phosphate, 200 pounds per acre.

7. Soil with nitrate of soda and sulphate of potash, 200 pounds each per acre.

8. Soil with nitrate of soda and acid phosphate, 200 pounds each per acre.

9. Soil with sulphate of potash and acid phosphate, 200 pounds each per acre.

10. Soil with nitrate of soda, sulphate of potash, acid phosphate, 200 pounds each per acre.

11. Soil with nitrate of soda, sulphate of potash, and acid phosphate, 200 pounds each per acre, with lime, 2000 pounds per acre.

12. Soil with cowpeas, 5000 pounds per acre, with lime, 2000 pounds per acre.

It is important that the small portions of earth be fertilized in the same proportion as is here given for the field, so to 7¾ pounds of dry, finely pulverized soil, add one ounce of any one of these fertilizers. Mix very thoroughly and pass it through a sieve at least

twice. This is still much too strong for use, so take one ounce of this fertilized soil and add it to five pounds more of soil, mixing and sifting as before. Then you have soil and fertilizer mixed at the rate of 200 pounds to the acre. For testing larger applications, make your first mixture with proportionally larger quantity of fertilizer.

For mixing lime with soil, take only 11½ ounces of soil to one of lime for the first mixture; for cowpea vines, four ounces of soil to one of vines, and only 1½ ounces of soil to one of manure. One ounce of each of these mixtures to five pounds of soil will give the right proportion of each to the acre, or, one ton of lime, five tons of cowpea vines, and ten tons of manure to the acre.

After you have added the fertilizers to the soil, it is left standing in pans or boxes for several days, being watered with rain water or melted ice water and frequently stirred. Do not use well or hard water, for those contain lime or salts, only rain water. Moisten the soil at the end of a few days until it is in the best condition for planting seeds. You soon learn to judge this.

Divide the soil in each pan into five equal parts and put one part in each of five wire baskets, pressing it down at the bottom and sides. After this is done, brush off the soil that has been forced through the mesh of the netting. The basket should be filled to within one-half inch from the top. The baskets are now ready for planting.

A couple of days before planting, put wheat grains between moist cloths, cover with wet sand and place in a warm spot to start germination. Take from these sprouted seeds those that are of the same size and development, and plant six in a straight line in each basket, being careful to plant all to exactly the same depth. Then cover the soil in the basket about one-fourth inch deep with clean, dry sand, dip the whole basket, down as far as the rim you have already coated with paraffin, into melted paraffin; cool, and dip again and again until it is completely covered with hardened paraffin for about one-sixteenth of an inch, and you have nearly completed your task.

See that the pots have the best possible conditions of light, temperature and moisture, as nearly as you can make it like what they would have in the field, being careful to keep all the baskets of one set together. Water them frequently. If you have weighed some of the baskets as soon as planted, you will know how much water to supply, for you must keep weight as close as possible to what it was at the beginning.

Fifteen or twenty days are enough to show you what fertilizer your soil most needs, and you can then go ahead and get it ready for crops. This is a test solely for soil needs, not for plant requirements, so it is not necessary to grow the plants any longer than just to show which basket flourishes best. It holds good in the field as well as in the basket.

One thing must be borne in mind, that weight must be accurate. If the farmer hasn’t time or patience probably his wife would make the test. She has time and patience for everything that is put upon her.

CHAPTER XXVIII.

MORE ABOUT FERTILIZERS.

In the past we believed that fertilizers acted as plant foods and that the substances to be applied must contain one or more of four elements which are probably the most important to the plant, namely: Nitrogen, phosphorus, potassium and calcium. Several other elements go to make up the plants; but these are considered most difficult for the plant to secure from the soil and were therefore of the most importance for the farmer.

Trials, by experimental work with different plants, soon showed that the forms of combination of these elements make a great difference. For example, nitrogen is now applied either in the form of nitrate of soda and of potassium, which is called saltpetre, or in the form of sulphate of ammonia; or, it may be applied as organic matter in dried blood, tankage, hoof- and horn-meal and even muck.

Both the nitrate and sulphate forms are readily dissolved, but the nitrate form is the one in which plants take up their nitrogen, so that either nitrate of soda or saltpetre is specially valuable for forcing a quick growth. The effect may be seen upon plants in a very few days after it is first applied. But sulphate of ammonia, although it will dissolve, must be changed into a nitrate, in the soil, before the plants can use it, and this probably takes several days, hence, it is not quite so quick acting.

The organic forms of nitrogen vary much in their usefulness. The nitrogen of dried blood or tankage is the most easily absorbed. These substances are sometimes sown at seeding-time, and become useful later in the season when the soil becomes warm. Other forms, however, as muck, leather parings, etc., are used considerably in making some low-grade fertilizers. Notwithstanding

the tradition that you must bury an old shoe at the foot of the vine, the nitrogen in these may never be of very much value.

The phosphorus is found in fertilizers both in forms that will dissolve and in forms that won't. Acid phosphate and dissolved bone contain a large portion of phosphorus in the form of a soluble phosphate of lime; this is often marked on the bag as being equal to 12, 14, or 16 per cent. of phosphoric acid. Ground phosphatic rock, also called "floats," and raw bone-meal contain phosphorus combined with lime in the form of an insoluble phosphate.

Basic slag is still another form of phosphate of lime, which, although insoluble, readily becomes available as plant food in the soil.

Potassium occurs in various forms of combination, one of the most common being muriate of potash; another form is sulphate of potash. Kainit is another fertilizer which contains potassium, and wood ashes contain a small percentage. In all of these the potassium is generally spoken of as potash and the first two are said to contain the equivalent of 50 per cent. potash. Kainit usually contains 12 to 14 per cent. Wood ashes may contain about 3 to 6 per cent. Kainit and muriate of potash have an acid effect upon the soil, and it is wise to apply them some time before the crop is to be sown, even the fall previous, if the soil retains plant food fairly well.

The commonest kind of calcium is quick-lime or lump lime. When this is "air-slaked" it becomes what is called carbonate of lime. Fifty-six pounds of lump lime contain the same amount of calcium as 100 pounds of air-slaked lime, and in using these it makes very little difference whether we apply the quick-lime or the air-slaked, provided we apply equal amounts of calcium and that the particles are equally small in both cases. In other words, 56 pounds of quick-lime or 100 pounds of air-slaked lime may be used, but both should be in as fine powdered form as possible before they are sown.

Like every other fertilizer, lime is of no use until it is dissolved, and the finer it is ground before it is applied the further it may be spread and the sooner it will dissolve. It is seldom wise to apply more than from one-half ton to a ton of quick-lime per acre at any one time; and it is safer to apply this quantity every three or four years rather than larger quantities at shorter periods. Lime should be applied to the land when there is a crop upon it which can use it with advantage. A crop like clover or alfalfa, which covers the land completely, will make the best use of lime. It may injure potatoes, because it makes the land more favorable for the growth of scab, a disease which attacks potatoes.

Much money can be lost by the unwise use of fertilizers, and the best way one can positively know whether it is wise to use them is to try it thus, say, with radishes, lettuce, or beans; a patch containing two or three rows may be fertilized in one way, the next one in another, others with various mixtures and, in order to determine the values of these it will be wise to leave untreated "check plats" between some of the strips. The following outline will show how to make such an experiment on about half an acre:

Plat 1.—Nothing[10] · · 2.—200 pounds nitrate of soda per acre in · two or three applications. · · 3.—600 pounds acid phosphate. · · 4.—Nothing. · · 5.—100 pounds muriate of potash. · · 6.—100 pounds muriate of potash and 200 · pounds nitrate of soda in two or three 198 feet.· applications. · · 7.—Nothing.[10] · · 8.—100 pounds muriate of potash and 600 · pounds acid phosphate. · · 9.—100 pounds muriate of potash. · 600 pounds acid phosphate. · 200 pounds nitrate of soda. · · 10.—Nothing.
…… 144 feet.

One hundred pounds per acre is one pound for 48 square yards, a strip, say, one yard wide and 48 yards long.

It may be necessary to repeat the experiment several years, before we can be sure what will give the best results; but we shall learn much that will help even during the first year.

In mixing fertilizers, care must be taken not to mix those which injure one another; thus nitrate of soda and muriate of potash, both take up moisture from the air quite readily, and when mixed with other substances are liable to make the whole mass pasty, or even to run together and bake in the bag; these should be mixed but a short time before they are to be applied. Nitrate of soda and acid phosphate, when they are mixed and allowed to stand, become damp and act chemically upon each other, and the result is loss of fertilizer elements into the air; the same is true when basic slag and sulphate of ammonia are mixed together.

We are frequently advised to apply fertilizers to the crop while it is growing. Nitrate of soda is generally used in this way, and to aid in spreading it, it is often mixed with acid phosphate. Now both of these substances, as well as muriate and sulphate of potash, are likely to burn the foliage of plants with which they come in contact; hence, broadcasting these over growing plants on a damp morning is liable to do serious injury to the foliage; it is safer to apply them with a drill.

Value in Fertilizers.—In estimating the value of fertilizers it is the custom to speak of the unit of valuation. A unit is one per cent. of a ton, or, in other words, 20 pounds. For example, if kainit contains 12 per cent. of potash and is sold at $12.00 per ton, then there are 12 units and they cost $12.00; therefore one unit costs $1.00, and since the unit is 20 pounds, the actual cost of the potash is 5 cents per pound. If muriate of potash, guaranteed to contain the equivalent of 50 per cent. of potash, is selling at $40.00 a ton, then we find that 50 per cent. potash is 50 units; if 50 units cost $40.00, one unit will cost 80 cents, or in this form 20 pounds cost 80 cents; therefore one pound will cost 4 cents.

Now, if these are prices free on board the cars at New York, and potash is the thing we need, we must remember that in order to get equal amounts of potash delivered to our own farm, we must pay freight and haul four tons of kainit instead of one ton of muriate of potash. In other words, with these figures the higher-priced fertilizer, counting in dollars per ton, is really the cheaper article, counting in value.

Any one who will secure the latest fertilizer bulletin from the nearest Experiment Station will usually find the approximate values of one pound of nitrogen, phosphoric acid and potash in the different fertilizers worked out in some part of the bulletin. These may be used in deciding whether it is better to buy and mix the fertilizers at home; then one may know what is going on the land and the form of combination it is in.

Manure contains all of the elements we have discussed in more or less fixed forms. The liquid manure from animals contains a large amount of the nitrogen passed from the body and is of particular value. The most useful parts of the manure are the ones which are easiest lost; hence, if manure is piled and allowed to ferment, or if the water from the roof of the barn is allowed to wash it, serious loss occurs.

A ton of fresh manure has all the value it ever will have, and if there is a piece of land upon which it can be spread, it should be done at once. The liquid manure should be soaked up by the bedding, and applied at once to the land. The holding of manure in piles or pits always causes loss of valuable elements. Sometimes we may have to hold it, but every effort should be made to arrange the crop so that it can be applied somewhere each day as made. Manure has a special value because it furnishes humus, which greatly helps the physical condition of the soil, and the bacterial and other microscopic life in the soil.

FOOTNOTES:

[10] NOTE.—If the yields of plats 1 and 7 do not agree closely, the effect of the fertilizer can be closely estimated by comparing the yield of each with the check plat nearest to it. Another interesting experiment is to lime one-half of each plat.

CHAPTER XXIX.

ROOT HOUSES AND VEGETABLE PITS.

In the North, we have to protect our gathered crops and to store them safely for a profitable market, but we do not need an expensive barn or cellar for that. A root house or vegetable pit will do instead.

This is the way to make one: in a warm, sandy or gravelly soil a pit is dug from one to two feet deep and sixteen or more feet wide, the length depending upon the crop you have to store. The sides of the pit are lined with one or two planks placed edgewise and held in place by stakes driven into the ground. Stakes are then driven into the bottom of the pit throughout its entire length; these support the ridge-pole four or five feet above the floor of the pit. Boards are laid from the edge of the pit to the ridge-pole to form a sort of gable roof. The support of these is strengthened by another girder carried by stakes driven half way between the margin and the ridge-pole. Then longer boards, from twelve to fourteen feet in length, are laid from the edge of the pit to the ridge-pole, slightly overlapping each other, and nailed lightly in place at the top ends. The pit being only a temporary structure, the boards are not securely nailed, as the same lumber will do for another pit next season. At distances of about ten feet some boards are left without nailing to serve as entrances, and at each place a stake is driven to mark the opening.

Such a pit will protect crops until severe freezing weather. After that, the board roof should be covered with straw, grass or other litter, and where the weather gets very cold, manure and earth are often added as the outer layer. The advantage of this pit is that it contains a large body of air which secures uniform conditions from day to day, and celery, leek, Brussels sprouts and even cabbage may be stored by setting in compact rows, so that they may make a slight root-hold and avoid shrivelling.

But there are many varieties of pits used for storing vegetables, and in Kalamazoo, the American celery centre, the favorite celery storage house is a permanent structure with windows at regular intervals along the roof, to give the necessary light for the workmen. These houses have wooden ventilating chimneys, and are usually heated with stoves so that the temperature may not fall below freezing point.

CHAPTER XXX.

SOME SMALL FRUITS.

The home garden would scarcely be complete without a strawberry patch, and hardly anything gives better returns. Strawberries grow in various kinds of soil, but a light, sandy loam gives the earliest berries, because that is the earliest, warmest soil. It takes only a few well-developed, well-cared-for plants to supply a family with berries enough, and the care is no greater than would be given corn. But you should make a careful selection of your plants. Small, weakly plants, or plants that have already been in bearing, are no good for your purpose. Therefore, buy from an honest dealer. Plants for setting should have been grown for that purpose purely, and not have been allowed even to blossom, as the important thing is to have a vigorous root growth, and well-formed crown.

This sort of strawberry plant will yield large, delicious berries about ten to fourteen months after setting out, and although a plot containing 100 plants requires not more than a half-hour's work a week to keep the plants in condition, after they have been well started, yet the yield will be about a quart to each plant.

To get such a return, you must first put your soil in good condition for planting. Have the soil finely pulverized and thoroughly fertilized with well-rotted manure, ground bone or wood ashes.

Having prepared your bed and got good strong plants, it is now time to set them out. Before doing so, trim the roots even, and cut off all but a leaf or two on each plant. The easiest way is to take them in bundles of 25, fasten together and cut the roots of all at once. But do not expose the roots to sun and air during planting. Keep them covered with a damp cloth. Lay the roots carefully in the ground, spreading them out fan-shape, and see that the crown of the plant is level with the surface of the soil, and firm the soil well around the roots. A properly set plant begins to grow at once, becomes larger and has more fruit crowns than a carelessly set plant. So be careful to start right.

Set the plants out in rows 18 to 24 inches apart, and 15 inches apart in the row. If each plant is set in a little hill by itself as you would set corn, you will find it easier to cultivate and also to keep the weeds down. It is as necessary to keep strawberries clear of weeds as it is any other crop.

Cultivate as soon as all the plants are set, and continue to do so once a week during the whole season. Pinch off all blooms the first year and cut off the runners. By so doing the plant will spend its energy on root growth and in producing more fruit crowns for bearing the next year. It never pays to crowd strawberry plants. Give them room and keep them in hills with cultivation and you will get both pleasure and profit from your patch.

It pays to mulch strawberries. As soon as the first hard frost has come, cover the bed with about three inches of litter of salt hay or straw. This prevents the ground freezing and thawing during the winter. In the spring you clear a space over each plant for the leaves to come through, but leave the mulch on the ground. It not only keeps the soil from drying out, but it also keeps the fruit from getting dirty from sand or mud.

From the first ripening, pick your berries as soon as they redden, every day if necessary, and let the picking be done in the early morning, before the sun has dried them. The berries keep longer and have a better flavor.

As soon as the plants cease fruiting, remove the mulch and cultivate. A handful of bone-meal mixed with the soil between each plant will have a good effect. In a few days the plants will put out runners. Allow one runner to grow from each plant, and layer this between the old plants in a straight row. "Layering" is covering the runner at one or more points with earth, or really planting it. It will develop roots at these points and become a strawberry plant. In from two to three weeks it will have got a good start, and then you can take up the old plants. In this way you can renew your own strawberry patch every year at little trouble or expense, if you get good plants to start with.

Some reference to the possible yields of strawberry beds has been made elsewhere in this book, so it will not be necessary to repeat here, but you will be making your own records soon, if you follow these simple rules.

Raspberries and blackberries succeed in any soil that is not too wet and heavy, and there are good profits in their growing. If you intend to take up the culture of these fruits, you will do well to read “Bush Fruit,” by Prof. F. W. Card. The bushes of both should be cut back and pruned in the spring, the raspberry being easy to handle with ordinary hand-shears, but a blackberry hook is better for dealing with the sharp thorns of that bush.

As soon as the fruit is gathered the fruiting canes of the season should all be removed; then in the spring, cut back all canes. This makes them stockier and stronger. They should be supported by wires stretched on either side and fastened to crossway pieces attached to stakes driven at each hill, for these fruits should be planted in hills, too.

Plantations are generally renewed every five or six years, although with good care yearly, they last longer. The yield varies from 1200 to 10,000 quarts an acre; the difference lies partly in the canes, and partly in the cultivation.

The home garden would scarcely be complete without currant and gooseberry bushes. They are easily grown, the gooseberry, in particular, requiring very little care and yielding large returns. It can be grown in clayey soil, though like the currant, it prefers a deep, moist, rich soil, especially a rich soil.

Strong one-year-old plants are the best to set out, and two- or three-year-old canes yield the best and largest quantity of fruit. All wood older than that should be carefully pruned. The same cultivation applies to both—well-rotted stable manure and shallow spring tillage.

The worst pest is the currant worm, which eats the leaves almost as soon as they unfold. Dust the bushes with powdered hellebore when the leaves are wet, or mix the hellebore with water and apply. Then there is the leaf blight, which attacks the leaves as soon as the fruit is ripe, and almost strips the bushes of foliage. This should be sprayed with Bordeaux mixture to stop its ravages, because if allowed to progress it weakens the bush, and the fruit next year will be small and of poor quality.

The grape-trellis is a common sight in the gardens of the New England and Middle States, but not so common as it will be when the gardener understands how comparatively easy it is to grow this fruit. A well drained, thin soil, with a warm southern exposure will provide for starting a good grape-vine.

The vine needs a trellis support always, and the pruning must be looked after, else the numerous runners will draw from the plant so that it cannot fruit properly. Keep the runners pinched off during the fruiting season, and in the fall cut off the old canes, leaving only the new, vigorous canes for next season. It may be two or even three or four years before much pruning is needed, but after that it must be attended to regularly.

Each new cane must have plenty of space, light and air, to prevent rot and mildew of the fruit, so that the number of canes you can allow to grow, depends upon the strength of the vine, the space to be covered and the root growth.

You may fancy other small fruits that you have room for in your garden. Any good agricultural paper will give you the information or name the book you need. Fruits are another means of making your plot pay, so you might as well grow a few at least.

CHAPTER XXXI.

THE POULTRY RUN.

Even the hen is intensively cultivated these days, and that makes room for her and her chicks on the small patch. It is perfectly amazing how little the ordinary farmer knows about poultry, although he has raised some, more or less, from time immemorial. The modern farmer is too wise to be caught with the extravagant stories found in some poultry papers, of the profits to be made from a hennery, though at the same time he is not wise enough to believe that with careful attention and improved methods, the hennery can be made to pay well.

It is for the benefit of the farmer who is neither too wise nor too ignorant to be taught, as well as for the villager and the intensive farmer, that this chapter is written.[11]

One of the new systems, Philo's,[12] extensively advertised, makes it possible for people with but little room to keep a small flock. By this system, the hens are always kept in confinement; but with some extra care and proper treatment they do well and yield great results; which is in harmony with the modern theory of intensive culture.

The first thing to be decided is what kind of poultry to keep. Chickens are the most popular of the various domestic animals suitable for the intensive farmer. Turkeys and guineas do not thrive well in confinement and are difficult to rear in a commercial way. Farmers who have free range, especially if they are adjacent to woodland, may do well with a few of these less domesticated birds. On the other hand, ducks and pigeons do even better than chickens in confinement, but there is less demand for the product.

The first essential for success with poultry, as with crops, is to secure good stock; the very best possible. To buy fowls simply because they are cheap is poor economy. Much better buy well-bred stock at five dollars and upwards, for they will not only give more eggs, but their brood will be worth more, so that in a year you can build up a fine flock of your own.

The second essential is to keep them in small companies, not more than six hens in a pen; still better results can be had with four. These are the days of intensive culture and chicks will respond to it as surely as field crops. Like the crops, they need abundance of food, to force growth and vigor and egg production. Care must be taken in the selection of food, but you are always safe on lots of oats, wheat-bran and green stuff, with some lean beef now and then. Corn should be fed sparingly to heavy fowls, but is an excellent diet for Leghorns or for any chickens on free range. Running water, or plenty of fresh water should be furnished. An open water vessel is best, although almost any self-feeding fountain is good. Place it about ten inches from the floor that no dirt may be scratched into it.

Fresh air and sunshine are necessities, but drafts should be avoided. Cleanliness is vital; if only a few hens are kept, all droppings should be removed every morning, and sand or lime or ashes sprinkled on the roosts and boards. If the food is good and well balanced, the premises kept scrupulously clean, and the fowls protected from storm and wind you will not be greatly troubled with disease or weakness. Daily care, never slackening, is the price that must be paid for success.

The poultry house should be in a sunny spot, on a hillside sloping to the south, if possible; but no one need be kept from chicken raising if such a spot cannot be had, for many successful plants are not so well situated. A light sandy soil offers the same advantages as a southern slope. Such locations or soils are not only much dryer but also much warmer, for the snow melts and the frost leaves the ground earlier in the spring than on northern slopes or in clay soils. The advantage of this earlier season is just as real as in a more southern latitude.

One of the main defects of poultry houses has been that they were built for people, rather than for hens; being too high, they are not easily kept warm in winter. The house itself should be well built to exclude storm and wind, but the southern side should be largely enclosed with muslin, which is much better than glass, as it affords an entrance for air without draughts, and furnishes plenty of light.

The roosting room may have a ceiling close above the roosts; this can be made of round poles or narrow boards, laid an inch or more apart, and over these there should be spread a covering of hay or straw. This will give ventilation, and yet retain most of the heat, especially if a thin muslin curtain is placed before the fowls during the night.

In the warmer localities, on the Atlantic coast from New York south, and in the Mississippi Valley anywhere south of St. Louis, curtain fronts are not necessary, but, instead, a part or all of the south side of the poultry house is made of poultry netting.

If chickens are to be raised in large numbers, incubators must be used; those holding two to three hundred eggs are most commonly used. After the chicks are hatched, comes the serious question of brooding them, especially during the winter. All kinds of little chicks need air and sunshine even more than older folk, and not many buildings allow of either; consequently, we must consider brooding out of doors, where air and sunshine can always be had. Fortunately, the experimenting has been done by others, so now we may avail ourselves of the knowledge they have gained, as many successful people are doing.

With properly constructed brooders and brooder coops, it is perfectly practicable to care for chickens from hatching to full growth, out of doors, at any time of the year, without artificial heat. This does away with all danger from fire and over-heating, and gives the chickens a vigorous constitution that will enable them to withstand all the ills to which chickens are liable.

These suggestions are not given as great discoveries, but they are a brief summary of the practical points of chicken raising, and are all workable. Some of them are given by the Rev. W. W. Cox, as the results of years of personal experience in the business. He

is now making a specialty of raising White Orpingtons, and is brooding out of doors, with success.

There are many branches of the “chicken-tree,” the more important ones being breeding stock, or fancy poultry; egg farming, broiler farming and roaster growing. Running a public hatchery, and selling day-old chicks, is the latest development, and is indeed so intensive that it links manufacture to farming, for the building site is the only ground required. These branches are recommended to the inexperienced poultryman in the following order:—1st, Egg farming; 2d, roaster growing; 3d, fancy poultry; 4th, broiler production.

Egg farming, properly conducted, is profitable in almost any locality. Roaster farming has proved a great success near Boston, but has not been largely introduced into other localities. Fancy poultry is a money-making game for those who are successful in winning prizes at the show, and getting well advertised as breeders. The broiler business, seemingly the most profitable branch, has in practice been a source of loss to many investors. The cause of failure in the broiler business, lies chiefly in the difficulties of artificial incubation, especially in the winter season.

Incubation is to the chicken raiser what the hot-bed is to the tomato raiser. If incubation is a failure, the whole business must fail. For the poultryman with a few dozen, or even several hundred fowls, hatching with hens is to be recommended, unless he keep Leghorns or Minorcas; these varieties not being good brooders. Convenient arrangements for setting hens in large numbers will be a more successful investment than incubators. For duck farms or Leghorn egg farms, or any poultry business on a large scale, artificial incubation is a “necessary evil.”

The Central Hatchery, only now being established here, although in use in Egypt for centuries, promises to solve this difficulty. The advantage of centralizing the hatching is that it admits of better methods than are available on a small scale, and also allows one man to devote his entire energies to this feature. Such hatcheries may be handled either by private individuals, or, as in the case of the creameries, may be co-operative institutions run for the good of the whole community.

A continuous house can be built with small compartments for each flock, and separate runs for summer use, though the colony plan is preferred by some, and has its advantages, among them being the fact that the flocks are more widely separated, so there is less danger of any disease spreading; and if any particular house becomes infected, it can be cleansed without disturbing the whole plant.

The colony plan requires considerable less expense in housing and other equipment than the yarded plan. The expense for food is also decreased, because of the greater number of insects and green food that the hens get from the range.

The following plan of poultry keeping is, perhaps, the simplest known, and for that reason, the most successful. By “successful” I do not necessarily mean the most profitable, but the surest of paying a reasonable profit. The plan is that of using inexpensive colony houses, which are located in a large yard or small field. These houses are built very light; they are floorless, and are moved frequently, either by team or by a pole-pry. By this method the droppings are distributed directly on the soil without the usual laborious work of scraping the dropping-boards.

In the poultry field some green crop is kept growing as much of the year as possible. As a general rule a crop cannot get a start in a poultry range, and so a plan of rotating the chickens in two or more fields, is desirable. No more profitable combination of “small” farming can be found than that of rotating poultry with the leafy vegetables (lettuce, spinach, cabbage, etc.) which utilize to the greatest advantage the rich, nitrogenous manure. Under this system, the hens are fed grain, chiefly corn, and beef scrap in hoppers, and water is supplied in the simplest way possible, preferably from a running brook. The chief point to be kept in mind is to cut down the number of necessary visits to the poultry houses, thus reducing the labor cost.

The custom of raising chickens on fresh ground every year is of value to the farm, but the one disadvantage has always been the expense of fencing. In a recent issue the _Rural New Yorker_ told of the plan of one wide-awake chicken raiser which can be followed by anybody. His plan is to sow sunflower seed with a drill, at the earliest possible moment in the spot where you wish the fence to be; then drive stakes at intervals along the row and stretch two-foot chicken wire over them. Even the wire will confine the chicks when they are small, and by the time they have grown big enough to get over that, the sunflowers have grown up and made a “chicken-tight” combination. Hens are too stupid to think of flying over such a barrier, yet the poultry raiser can come and go as if there was no barrier.

This is not only a cheap fence, but it affords the necessary shade for the fowls in hot weather. They lie about among the stalks scratching in the cool earth and getting a dirt bath at any time in the day. Then late in the season the sunflower heads are cut down

and the pullets do the harvesting of that crop in short order. No other variety of fence can be used for food when its usefulness as a barrier is past. You could easily put up this sort of a fence yourself, and as the sunflower is a very hardy plant, you might even try sowing the seed in the fall, so as to get an early start in fence building in the spring.

You must be willing to give your time and attention if you are to succeed. One man who has had a good deal of experience writes me about the new method of chicken raising as follows:—"No doubt it is a valuable contribution to the subject of intensive cultivation of poultry. It involves, however, the most intensive and persistent labor, to which very few men are willing to subject themselves, and I am one of that class. I have had enough. Still, I need more income, and I am thinking, just a little, of Indian Runner ducks, which demand cheaper buildings and less care than chickens. Yet I cannot raise much enthusiasm on the subject, and I shrink from the constant attention to details which even they require."

But even if you are not prepared to raise fowls after this fashion, there is no reason why you should not keep a few hens and raise a few chickens for your own family use. If you hatch in incubators, use eggs that are laid the day you put them to hatch, and with good management practically all of them will produce vigorous chickens that can be induced to lay early, if pullets, and can be fed for market, if cockerels.

Eggs are more profitable than chickens, especially if you can produce them out of season, and this depends upon the time of hatching, the feed and care. A flock of 25 fowls will produce eggs and chickens enough to add a tidy sum to the income, if you feed and house them right. And the feeding need not be much of an expense, if you save the table scraps and give corn, cabbage and other green stuffs, buying whatever wheat and oats you can't raise. In winter, change their drinking water frequently and see that it is slightly warmed. If you cannot provide running water, then you must give them clean water many times a day all the year around.

As a matter of fact, the amount of effort expended is pretty closely related to the profits to be derived. Whether you raise hens, ducks, geese, squabs, or any of the many animals now raised for profit on the home acre, you must study their needs just as you must study plant needs, if you are to succeed. Only by the use of intelligence can you expect to reap profits, and to natural intelligence must be added study. A man could not expect to be a successful teacher of mathematics unless he had studied all the authorities in his special line, and kept himself in touch with all the new theories as they were advanced. So it is with the farmer. If he does not read the papers that deal especially with his calling, he cannot keep in touch with the improvements and discoveries constantly made in his line. He should take in at least two standard agricultural papers. In a community where there is no public library, the farmers might agree among themselves to take one or more different papers each, and then exchange. In this way they could keep in touch with all, at the expense of only one or two.

It will not be worth while for anybody to take up this work with any hope of success, who expects to go at it with "a lick and a promise" idea. It is only by thorough, careful, intelligent and persistent effort that anything worth while can be accomplished. For the person who will undertake the task in that way, there is an opportunity; but he will need to have patience and some money while getting started and learning the business. By all means, start in a small way, and find out a lot of things which only experience can teach you; after that you can gradually increase your plant with comparative safety.

FOOTNOTES:

[11] NOTE.—This chapter has been specially revised by Milo M. Hastings, the author of a new and thorough work, "The Dollar Hen." Mr. Hastings was formerly the commercial poultry expert of U. S. Dept. of Agriculture.

It will be impossible in the brief space available to go into detail concerning all the up-to-date methods of poultry production. I can only call attention to the system by which the industry is being modernized and by which, also, it may be made to yield handsome profits to the intelligent and aggressive poultryman.

[12] NOTE.—These systems mean small numbers together. A few eggs in the incubator; a few chicks in a brooder; a few youngsters in a colony coop; a few layers in a small house. The Philo poultry plant covers 40 × 40 feet.

CHAPTER XXXII.

ORGANIZATION.

We hear a great deal about the farmer waking up to the fact that his calling is a business that must be conducted upon business principles, if it is to pay. Anybody who knows anything about the farming methods, or lack of methods, of the past, will recognize

that this awakening has not come a moment too soon. Neither is the farmer wide enough awake even yet. But the feeling is growing, and much of the credit is due to the farm papers, the agricultural colleges and the writers of books on farming and gardening on a small scale.

Somewhere, hidden in the heart of almost every man, is a longing to own a bit of land and grow vegetables or fruits; and it is to this man that the new order of things means most. He has had business experience, and will naturally apply business principles to anything he takes up.

It is not many years since agricultural colleges were looked upon with amusement, if not with scorn, by the very people whom they were intended to help. The “scientific” farmer was classed with that other hopeless being, the “book farmer.” But the colleges and books kept on doing their work, and the college-bred and book-made farmer kept on doing wonderful things with soils and crops, and now there is scarcely a farming community that does not number among its leading members a farmer of one or both sorts. So does time work changes.

Boys who intend to be farmers are now sent to agricultural colleges, and the wise farmer takes in good agricultural papers and reads agricultural books. He has organized himself into granges and other associations and is fast learning the value of co-operation. All this tends to elevate his calling, a calling which is naturally more dignified than any other, and to make himself and his labor of more real value to himself and to his fellows.

But even yet there is too much haphazard arrangement of the farmer’s work, and for this reason he is always struggling and finding little leisure. It is partly due to the lack of organization in his work. If he has not too much land, and if every month has its appointed tasks, the farmer will move along from task to task, with at least as much leisure as his city brother. So get your work mapped out, and attend to things as they need attention, instead of leaving a lot of small things to pile up and in the end cause hurry and confusion.

Plan your work and work your plan.

In the month of JANUARY prepare for spring work in your garden. Whether you devote your plot to vegetables or fruit, lay it out now in your own mind or, better still, on paper. Get catalogues from seedsmen who advertise. Most of them get their catalogues out in January. They are business men and know the value of an early start. Make up your mind what you want to grow, being sure to plan for plenty of the things you eat,—and then select the things you mean to experiment with during the coming year. Follow a well-arranged planting-table, such as was published in _Suburban Life_, of New York City, in March, 1908.

If you have fruit trees on your plot, this is a good time to begin to spray them. If you don’t get ahead of insects and diseases, they will soon get ahead of you. If you intend to do any grafting, secure the scions now and keep them buried in sand in a cold cellar, or even out of doors, until the sap begins to rise in the trees. Then you are ready to work without loss of time. If there are holes in the trees, clean them out and fill with cement. You won’t have time for this in the spring, and the gypsy-moth, or some relative of his, will select the hole as a ready-made breeding-place. Paint all wounds or breaks in the bark with good paint or tar. On warm days do the necessary pruning.

Look out for your live stock, even it if be only the family horse and cow. They will serve you better for careful attention. Warm the bit on cold mornings before putting it in the horse’s mouth, and look out for signs of possible toothache. He suffers from that as well as you. Have him sharp-shod for slippery weather. If the barn is cold, blanket your cow as well as your horse, give her plenty of warm bedding and see that she and the horse have salt at hand at all times. Don’t give either animal ice-cold water to drink. Take the chill off it. A hot mash will not do either of them any harm on a cold day. You like hot food in winter.

Look after the comfort of your poultry. Dust them well for insects. Give them fresh, slightly warmed water every few hours during the day. Vary their food somewhat and give some corn and meat-scraps. Be sure the meat is good, as spoiled scraps lead to disease. See that they have green food, and as much exercise as possible; keep their house clean and well ventilated, but free from draughts. If you are going to raise broilers, get your incubator busy, but it is too early for hatching chickens for layers. If you have no incubator, but mean to get one later, read up all about them now. Don’t buy blindly.

Get out your fencing stuff, if you have fences to build; and read up all you need to know about your soils and the value of fertilizers, etc. Don’t wait until spring to know what it is best to do with your plot. Learn that in advance, so that when spring comes you may put your knowledge into practice without delay.

* * * * *

The same general instructions hold good for FEBRUARY. Give constant care to your stock whether many or few. See that your tools, planters, sprayers, plows, etc., are all in order. Many valuable hours are lost in gardening-time because of neglect of this precaution. Repair those that need it and are worth it, and consult catalogues for the new machinery you must buy, and buy only the best of its kind.

If you are using hot-beds or even cold-frames, you can prepare them and begin to plant some seed during February, such as radishes, lettuce and early cauliflower.

* * * * *

MARCH is still too early for out-door planting in the North, because if the seeds get chilled, they will be slower in growth than those planted later; but well-made hot-beds are getting in their good work at this time. Eggplant, tomatoes, early cabbage, onions, parsley, peppers, etc., are all to be started before this month is out.

If the ground softens up so that you can go out on it at all for working, you may sow your grass seed and spring oats and barley that they may get the advantage of spring rains and be well grown before the dry, hot weather sets in. You find many farmers neglecting their stock at this time of year, but it is bad policy. Keep up their rations.

If the storms of winter have strewn your plot with branches of trees and other wreckage, clean it all up; the wisest plan is to burn it. Clean the out-buildings; sort over your seed, and see if any insects have got at them during winter; test them between moist papers or cloths as described, to see which are worth planting; clean out vegetable bins, burying all decayed vegetables. Be ready to take advantage of the very first of the out-door-planting weather. Every day of preparation now counts for three in results.

* * * * *

APRIL is a busy month in farm and garden. Preparation-tillage is in order, if the ground is not too moist. Too much stress cannot be laid upon the importance of thorough preparation of the soil before the planting begins. What you neglect in this line cannot be made up later in the season, and you will suffer in field and pocket. Be sure that your soil is neither too wet nor too dry when you begin operations, and when you are through, be just as sure that it is thoroughly pulverized and fertilized, so that it can retain moisture and afford the right bed for the tender seeds. Then plant all the hardy crops as directed in the chapters on crop raising in this book.

Get your neighbors to co-operate with you in clearing out neglected roadside corners and in destroying weeds. It will pay. All the crops in the neighborhood will profit from this action. Don’t turn the stock out to feed until the grass has made some growth. You don’t want the roots gnawed out.

* * * * *

Even in the northernmost parts of the New England States, much of the out-door planting is done in early MAY and the rest a little later in the month. Now is when you begin to realize the value of having done all your preparation work early. Planting potatoes, peas, beets, cabbages, turnips, to say nothing of beans, corn, pumpkins, squashes, cucumbers, etc., will take all your time every day that is not spent in cultivating and using the wheel-hoe. Besides, your strawberry beds will be needing a good deal of attention, and your chicken-run should have its location changed for awhile.

* * * * *

There are no idle times for the intelligent farmer, but the beautiful month of JUNE is generally the busiest. Indeed, it is often so busy that the farmer does not have time to know how beautiful it is. But you can have time. Arrange your work; drive it instead of letting it drive you, and you will be surprised how much time you have to look up and to realize that it is a glorious thing just to be alive. But this cannot be if you have neglected your work from month to month. The smell of ripening strawberries, of new-mown hay fill the air before this month is gone; the sky is the bluest, the grass the greenest, the trees the freshest of any month in the year. Don’t lose those delights without having known that they have come. Cultivate yourself as well as your soil, and life will be better worth the living.

* * * * *

JULY is the real haying month in the Northern States. There are scores of things to do. Many of the fall-crop vegetables are to be sown this month, and the ground must be put in good condition as soon as the early crop is off. But busy as you are, it is good to take a day off occasionally and see what your neighbor is doing. Perhaps he has some scheme by which he has forced his crop ahead of yours. If so, compare notes and learn what you can.

* * * * *

In New England they sow the winter crop of turnips in the early days of AUGUST. Be careful that the root maggot has not got into the ground where you plant them, for, if he has, you would better save yourself the labor of planting in that spot. You want to starve the maggot, not to feed him. Cultivate all your crops carefully this month. Perhaps they didn't get all the attention they needed during haying, and as the weather is apt to be pretty hot and dry, you must do all in your power to keep the moisture. Therefore, good maintenance-tillage is in order. Cut down the weeds on the roadside that have escaped you before. It is a costly mistake to allow them to go to seed. You will have to work a good deal harder and get less for it next year if you let them go to seed this year. "One year's seeding is seven years' weeding."

* * * * *

If you have fruit trees, SEPTEMBER is one of the finest months in the year, both for the looks of your place, if it has been properly kept, and also for your profits. The early fruit brings good prices, and if you have shown foresight in planning out your garden, you have planted some fruit trees that will pay you. Harvesting begins this month, and you want to be sure that everything is in readiness. Have your bins and cellars thoroughly cleaned and aired, so that there may be no delay when crops are ready to be stored.

* * * * *

OCTOBER calls for extra care for your fruit trees, because frosts are to be expected. Winter apples should be picked before they are fully ripe and kept in a cool place, but where they cannot freeze. If you intend them to last all winter and into the spring, you should sort and pack them carefully, seeing that no bruised fruit gets into your barrel or box. One bruised apple in a barrel may cost you half a dozen or more of the finest.

* * * * *

Although in some places it may be necessary to begin fall plowing earlier than NOVEMBER, yet, generally speaking, this is the month for that work, and unless frosts come early, you can plow about all through the month. It is the month for finishing up the fall work and getting ready for winter. There is no better time for gathering up whatever rubbish may have accumulated—all the vines and garden waste that you cannot use for plowing under—and making a bonfire of it. That is a work the boys will delight to help in, and if you will save the actual burning for evening, you will make them extra happy, and glad to do some more cleaning up. Work is best done in the way that brings the greatest amount of pleasure.

* * * * *

DECEMBER has its joys and its work as well as June. The stock are almost always shut up now and get only what you give them, either to eat or drink. Be careful to keep their troughs scrupulously clean, and occasionally feed both horses and cows a little molasses. To keep the stable well ventilated, take out a window and fit in a frame covered with muslin or cotton sheeting. This will help out the ventilation and shut out the draughts. If it is hinged at the bottom, so that it can be opened on clear days, it will be all the better.

And now just a word for man's other faithful friend, and the children's guardian, the dog. He feels the change in the weather, too. If he should begin to scratch his ears or rub them on the ground, clean them carefully with lukewarm water in which bran has been boiled, and add a little white castile soap. When you have rinsed and dried them dust a little dry boric acid into them. He'll be more comfortable and so will you. Stonehenge or Youatt "On the Dog" will tell you all about him.

See that your farming tools are all well housed where neither rain nor snow can get at them. If you were too busy to thoroughly clean and oil them before putting them away, do it now. The long winter evenings will afford you plenty of time to read up on any matter in which you are interested. At the end of the year you will be astonished to find how much you have accomplished without being rushed or overworked, just because you organized your work and followed a definite plan. Like all other good things, it pays.

When we are exhausted or rushed, it shows that either we have been doing the wrong thing, or doing the thing wrong.

CHAPTER XXXIII.

A FEW PRACTICAL “DON’TS.”

Don’t imagine that you cannot do anything with a bit of ground. You can.

Don’t run away with the idea that the farmer’s life is all fun or all labor. It isn’t. It is a mixture of both, and fun and labor are equally healthful and profitable.

Don’t think that breaking up the surface soil for an inch or two is the same as plowing. It is not. The old proverb is good advice for the farmer—“Plow deep while sluggards sleep.” To plow in the fall is to lessen your spring work by at least a third. Spring plowing is easier because of it, and the work of the harrow is lighter.

Don’t begrudge manure. All forms of life require food. If you want your plants to grow, feed them.

Don’t plant tiny, tender seeds in hard, cold, lumpy soil and expect them to grow. They won’t. Pulverize your soil, warm it with sun, air and manure; make a cosy little bed for your seeds, and while they snuggle into it, they will be sending out little sprouts all the time to see what the rest of the world is like. Just as it is good business policy to treat your hired help as if they were human beings with feelings, instead of mere tireless machines, so it pays to make your seeds comfortable.

Don’t forget that your plants like air, and that what they get by their stems and branches is not enough. The roots have to breathe. So keep the earth about them stirred somewhat, that the air may get to them.

Don’t skimp the supply of moisture. Although you don’t want to drown out the seeds by soaking the ground, yet you must so till it that it holds all the moisture the plant needs. You find your craving for water greater in summer than in winter, especially if you are working hard. Well, the plant is working hard, if it is growing. See that it has its drink of water always at hand.

Don’t decide to let the weeds on the roadside grow, just because they seem “nearer the other fellow’s plot” than yours. There are no “other fellows” in a matter of this kind. It does not take long for the weeds he has to get to you. If he doesn’t know the importance of cleaning even the road, and you do, just set him the example. He’ll soon ask you why you did it. After that, he’ll probably do his share. At any rate you will have done yours.

Don’t try to grow more and better crops than your neighbor, just for the “fun of getting ahead of him.” Grow them to prove how much can be done with your facilities, and to show him, as well as yourself, how much more pleasure and profit he can find in gardening than he has known before. Next year he’ll probably show you a thing or two.

Don’t think you have to emigrate to some far-away spot to make a living from the earth. All soil can be made to produce if you use brains as well as labor. Begin where you are, no matter how small the plot. Learn to do it in little before you try it in large. If you have no plot where you live, try to get the use of a vacant lot in your town or city. Put up a tent and live in it. You and your family will be the better for roughing it a bit. There’s lots of fun in camping if you go about it in the right spirit.

Don’t be afraid to ask advice from the Department of Agriculture. They are conducting their experiments for your sake, if that’s the sort of knowledge you want. If it were not for you and thousands like you, they would not need to discover so many of Nature’s secrets. Get the benefit of their discoveries.

Don’t think you can farm without proper tools, any more than a man could print a paper without a printing press. The old-fashioned, small hand-press, would stand a poor show beside the new power presses. So with old-fashioned, hand-gardening tools. You can do more work with a wheel-hoe than with ten hand-hoes, and it isn’t so painful either. Get only the tools you need, but be sure to get them, and get the best of their kind.

Don’t let your tools stand out in all weathers, and don’t forget to clean them and see that they are oiled. A dirty farm implement may mean the spread of disease; unoiled bearings may mean injury from rust or breakage. Save time and expense by a little care.

Don’t expect eggs from dirty or ill-fed fowls. The natural returns from such conditions are vermin and sickness; and you’ll get them.

Don’t expect to take everything out of the soil and put nothing back. The soil is like a bank account, so long as you keep adding to it, you may draw from it. But if it is all “draw” and no “add,” then you will soon come to the end of your resources. Feed your soil and it will feed you.

Don’t plant poor seed. You can’t afford it. The best is cheapest. If you have poor seed on hand, throw it away—or perhaps it might do for the chickens. No loss can be so great as the loss of planting it.

Don’t forget that women are apt to make good gardeners, because they are willing to “fuss over” necessary small matters. If you do not like to attend constantly to “little things,” if you “hate details,” you will be unlikely to make a big success of intensive culture. The man who does best is the one who loves to compare soils and fertilizers and seeds, and to try how many seeds sprout and how long they take; who is interested in the temperature of every hot-bed; who watches for just the day to use the wheel-hoe on this row and the hand-plow on that; who finds the time only too short while he sets out onion seedlings; who enjoys putting up nice bunches of vegetables or packages of fruit. In short, the man or woman whose interest is in watching the crops instead of the clock, is the one who succeeds in garden work.

Don’t delude yourself into thinking that you must have a fine house before you can take up gardening. A shack is as good as a palace, and better, if you can afford the one and not the other. Anything that can be ventilated and made weather-proof will be enough. After you have made your fortune, if you have not in the meantime learned the value of simple living, build your fine house, and be as splendidly uncomfortable as even the worst Philistine could desire. But while you are earning your fortune, be comfortable. It pays.

Don’t think you must throw up your job and rush into farming for a living, unless you have had some experience, or have a snug little bank account to depend upon while you are learning. Get your experience on a small piece of land first, while still holding down your present job. Be sure you like the work and that you are willing to give all necessary time and attention to it.

Don’t think that this list exhausts all the “don’ts,” practical or otherwise. There are dozens of others. But it is well to leave something to the imagination and to experience. You’ll learn them for yourself and remember them better for it. Nevertheless, it will do no harm to attach the rules for farm buying submitted to the American Jewish Association. They run as follows:

Don’t think about buying a farm if your wife won’t live in the country.

Don’t believe in agents when they tell you gold-brick stories.

Don’t chase after big farms.

Don’t buy a farm unless you have money enough left to buy a cow.

Don’t run too much in debt when you buy your farm.

Don’t pay a deposit on your farm until you have consulted a lawyer.

Don’t forget to insure your farm buildings in a reliable company.

Don’t buy a farm unless you are able to meet the mortgages.

Don’t buy a farm unless you have consulted those who know.

Appendix I.

The island of Guernsey in the English Channel, only from four to seven miles long, and three to four miles wide, supports a permanent population of 41,000 and an additional visiting population each year of about 30,000 persons. Only 11,623 acres are under cultivation, but if the glass houses and frames were placed in line they would extend for twenty-eight miles, or all around the island, and up the centre for almost its entire length, and would average about 10 feet in width. The farming lands are valued at twelve hundred dollars ($1200) an acre, and are rented at 10 per cent. of their value. The exports of this land in fruits, vegetables, flowers and cattle, amount to more than two and three-quarters millions ($2,752,000) annually. In addition to this, the farmers produce all that the 71,000 persons consume, as well as hay, oats and forage for horses and cattle; and about $500,000 worth of butter, poultry, eggs, pork and beef. At a conservative estimate, the island produces about four and a half millions’ ($4,500,000) worth of farm and garden stuff each year, or a little less than four hundred dollars’ ($400) worth to the acre.

Don’t you think we Americans, with our improved machinery and intelligence, can get much more out of our land—when we try?

If the State of New York were all cultivated and populated at that rate it would produce nearly $15,000,000,000 worth annually and sustain 233,641,473 people, or about three times the population of the entire United States. So we are not going to suffer from “over-population” or “pauper labor” just yet.

Appendix II.

French Gardening, and Other Gardening Under Glass.

Intensive cultivation reaches its climax for the present in what is called the French System, in vogue in and about Paris, and in some parts of England, where rents are so enormously high that even an inch of space counts, and must be made to produce its utmost. It has not been in favor in this country, because, so far, the pressure of rent has not compelled people to look so much after the inches. But, if the present land-tenure system continues, there is no telling when the French system of cultivation will become a necessity. In its simplest terms, the French system is hot-bed cultivation with perfect fertilization and irrigation, usually without artificial heat. The secret of it is—manure, unlimited quantities of it, of the finest quality and rotted to about the condition of leaf-mould. The beds are made on the top of the earth, the foundation being fresh stable manure that has been turned several times and thoroughly sweetened. Cover an area sufficient to accommodate the number of frames you intend to use, with great quantities of manure, so that after it has been tramped, pressed and rolled flat, it will be from 6 to 8 inches deep at least. Sometimes it is made two feet deep. The frames are then placed on this bed, the manure extending well beyond them on every side, and a distance of 18 inches is left between the rows of frames. A layer of fine, rich, dark soil, mixed with manure that has been rotted during the previous season, is then spread on, to the depth of six inches, pressed down and raked. The bed is then ready for planting. Generally four crops are grown in each frame, radish, lettuce, carrots and cauliflower being the usual combination.

The radishes are sown first, quite thinly, then a thin layer of carrot seed. These are covered with about half an inch of fine soil well pressed down. Cabbage-lettuce is next set out, the plants being placed nine inches apart, and, so far, three crops are growing at the same time. The fourth, cauliflower, is not planted until the radishes are off,—in about three or four weeks,—the lettuce has been cut and the carrots are showing well above the ground. Then three or four cauliflower plants are set in each frame between the carrots.

But one of the most interesting parts of this work is the growing of the lettuce and cauliflower plants for transplanting to the hot-bed frame. These are grown under “cloches” or bell-shaped glasses 17 inches across the bottom and 15 inches high, on a seed-bed prepared just as the hot-bed was prepared, except that the manure foundation is anywhere from 12 to 15 inches deep after being pressed down. These beds are not covered with frames, but the cloches are placed on them in two rows, and within the circles made by them the seed is sown.

As soon as they come up, they may be transplanted from the cloches to the hot-bed direct, or they may be pricked out under other cloches, four plants to a glass, usually one Cos lettuce and three cabbage-lettuce. These are again transplanted to the hot-bed where the radish and carrot seed were sown, and follow the radish in being picked. Lettuce seed is also sown in cold-frames about the first of October and successive sowings are made until the end of that month.

Immediately after the lettuces are picked the bed is watered and weeded, and among the growing carrots the cauliflower is set out. Cauliflower is grown under cloches, the seed being sown as lettuce seed is, under the glass or in the open seed-bed, from October to November, and pricked out under the cloches as soon as the plants are well up. They can be planted out in the hot-beds in February, and are ready for market between the middle of May and the first of June. About April the process of hardening begins, and by the end of that month the frames and sashes are removed and the beds stand in the open. During the time the crops are growing under glass, they need a great deal of attention, that neither the sun nor the frost may injure them. For this reason they are covered, uncovered and recovered several times during each day with mats or frames.

When the cauliflower is off, the bed is forked over and planted with endive, spinach, celery or other garden crop. When the season’s crop has been harvested in October, the soil is gathered up in a great heap, and the beds are topped with decayed manure in the leaf-mould state. This is the best thing to plant in, and if one had enough of it, the crops could be grown on a concrete floor; because in such soil plants find all that they need.

To bring it down to the fine point, the French system consists of manure, more manure, irrigation, availing of every ray of sunlight, and unremitting care. It requires three years to get the system in good working order, and here such intensive cultivation seems unnecessary. It shows what man will do in the way of developing the possibilities of nature, when by law or custom he is debarred from free access to the land, and must needs make a very small portion yield a great return.

We are not in much danger of Malthus's over-population, and the much-talked-of "pressure of population." Where so tiny a piece of soil can be made to support so many and give them a good living, too, it is foolish to argue that the cause of poverty is found in the increase of population. This country alone could support many times the population of the whole world today if natural opportunities were free. It has been said that 80,000,000,000 could then be more comfortably supported here than 80,000,000 now are. To find the cause of most of the poverty, and even crime, in the world, we must look beyond the population statistics to the restrictions and monopolies that prevent population from providing for its own needs from natural sources. And when once you begin to investigate monopolies, you will find the mother of them all—Land Monopoly.

* * * * *

A new sash for use in hot-beds and cold-frames has been placed on our market within a year or two, for which its makers claim many desirable things. It seems as if their claims were being well sustained by the experience of those using the Sunlight Double Glass Sash, as it is called. The frames are made of red cypress and are fitted with rustless springs and stops to hold the glass in the grooves and thus do away with the expense and bother of glazing. There is a space of dead air between the two layers of glass, which resists the cold from without, and prevents the escape of heat from within. The sash are sufficiently air-tight for ordinary weather, and when the thermometer falls, the moisture which has gathered between the two layers of glass, freezes and seals the sash practically air-tight.

The makers claim that Sunlight Double Glass Sash save more than half the labor, worry and expense of growing plants in cold-frames and hot-beds, and insure better plants, and, therefore, better crops, than can be secured under the same conditions from single-layer sash. They do away with the necessity of covering the frames with mats or boards, being warmer than the single-layer sash even though covered with mats or boards. Frames or beds filled with half-hardy plants, such as lettuce, cabbage or cauliflower, need no extra covering even in zero weather; and as far north as northeastern Ohio, with the thermometer nearly down to zero, even tomatoes, peppers and eggplants have been raised without additional covering, although this may not always be done. Light is never excluded from the growing plants by night or day, and in the short winter days of this climate, there is some advantage to that. Even when snow and ice lie on the sash, there is some light getting to the plants, and in clear weather the heat from the sun's rays during the day is stored up in the bed and held by the double glass with the air-space between. That is why even in zero weather the half-hardy plants need no extra covering.

It is quite possible that the gardeners of this country may make a system of their own for intensive cultivation, to equal and perhaps excel the French system with its repeated covering and uncovering of the frames. The sash are made in Louisville, Ky.

Appendix III.

At Maylands, Mr. Joseph Fels' "colony" in England, all the land is under intensive cultivation, and the rules for getting the best results from hot-beds are simple enough for anybody to follow. They emphasize the advice given in this book and are, therefore, printed as an appendix, so they may be easily consulted. They are furnished by the superintending gardener of Maylands, Mr. Thomas F. Smith, Maylands, Essex, England, for this book, and are as follows:—

GENERAL INSTRUCTIONS TO MAYLANDS SMALLHOLDERS.

"It is possible to put the frames to a variety of profitable uses during the winter and spring, but under the special circumstances of our community, and the arrangement for co-operation, it will be best for all to follow one plan, and the produce can then be handled in bulk. To this end, I suggest that the frames be used for radishes and cabbage-lettuce, then cleared for pricking out tomato plants; afterwards, during the summer, used for cucumber or melons.

"During the last week of September, prepare a bed of about a square yard by digging. Break it up fine; cover it with two inches of prepared, sifted, well-rotted manure and soil in equal proportions. Sow broadcast, thinly, a few inches of cabbage-lettuce seed—Watkin & Simpson's Early French Gold Frame will be very suitable. Cover with ¼ inch prepared soil and press evenly all over. Place a wooden framework round the bed and cover with a sash. Do not water. If the sun shines brightly in the middle of the

day, cover the sash, and uncover as soon as the sun's power is gone. In 4 or 5 days the plants will be up, and as soon as they can be handled they must be pricked off in frames standing on beds prepared in a similar way to the seed-bed, except that the soil inside must come half way up the board. Prick them out 2 inches apart, and do not water. They will stand here during the winter and the work now is to watch them carefully, remove any decayed ones or any showing mildew. If any mildew shows, dust over lightly once or twice with flowers of sulphur. Keep as dry as possible. In hard, frosty weather cover the frames with mats, but remove these whenever possible, and give air on very mild days.

"Towards the latter end of January prepare the hot-beds, by mixing well together equal quantities of old, dry manure and fresh manure. In both cases this must be 'long.'[13] Shake out the lumps and lay the manure down to the depth of 18 inches. Keep level and beat down gently with the back of the fork. Make the beds wide enough to extend at least 9 inches beyond the frames. Tread the manure down and level up any hollows. Lay the frames on straight and level. Fill up inside one-third the depth with similar manure to that used for the bed, then add 2 inches or so of the prepared soil. Rake the soil well, to leave it level and remove lumps. Put on the sashes and cover with mats. Any of this work must be finished the same day it is begun and covered up. This is of importance, as frost, snow, or rain might set in, and spoil the bed. The remaining beds must be made in the same way, all joining up so as to form one entire bed without any spaces between. The frames are butted together at the ends, and are set 1 foot apart between rows.

"Two or three days after finishing the first bed, it will begin to get warm, which may be seen by the damp inside the glass. Now sow radishes (French Breakfast Radishes—white-tipped) thinly broadcast. Cover them up lightly with dry prepared soil, well sifted; press down evenly. Set out the whole bed with lettuces at 9 in. apart. Before planting, the lettuces must be carefully examined, all decayed leaves removed, and doubtful plants rejected. Use only the strongest plants. Handle very tenderly, so as not to bruise them. Cover the bed every night with mats. When the radishes are up, give a little air on the opposite side to the wind, but be careful not to overdo this, as the lettuces thrive better with very little air. If any decayed leaves are seen on the lettuces, remove them. If the heat in the frames slacks, as may be seen by the radishes not moving quickly enough, place littery manure all round and between the frames up to the lights. The radishes will be ready for gathering the fourth week from sowing, and should be cleared off a bed within 10 or 12 days. When they are all gone, water the bed well between the lettuces with a fine 'rose'-nozzle hose. Choose a dull, mild day for this, between 11 and 12 o'clock. The lettuces will be ready for marketing five or six weeks after planting, which will be about the middle of March.

"About the beginning of March, make up a hot-bed for one frame of three lights or sashes. Make it two feet thick, and at least a foot beyond the frame all round. Fill up the inside as before, and pack round outside. When the heat is steady, sow the tomato seed, thinly, in rows about 1½ inches apart, keeping at least ½ inch between the seeds. Cover and press down, then scatter lightly all over, a sifting of fine rotted manure. Water well, cover up, putting mats on. In seven or eight days the seed should be germinated. Keep a watch on it and remove the mats the moment it is seen to be breaking through. Water gently with a fine rose, using chilled water. Give all the light possible now, and water as required, keeping the soil just nicely moist. As soon as the first pair of rough leaves show, begin to prick off; if the pricking off is not commenced early the plants will be getting 'drawn' before it is finished.

"After cleaning the beds from which the lettuces were taken, fork over lightly and add 3 inches more soil; press all down very firmly and prick out tomato plants 3 inches apart. Do not water. Keep close for a few days until the plants begin to move, and cover at nights. As the plants show growth, water gently and give air on mild days, gradually giving more water and air until the first week in May, when the lights may be taken off on all mild, genial days. By the middle of the month leave air on at night, and the last week the lights may be removed altogether. The weather must be carefully watched, as May is a very changeable and treacherous month; it is very usual for frosts and cold weather to return about the middle of the month, and protection must be given if necessary.

"The ground where the tomatoes are to be set out, should have been prepared during the winter by digging or deep ploughing; a moderate dressing of natural manure should have been added if the ground is poor, but the ground which has previously been heavily manured and cropped with vegetables will be preferable, no manure being added for the tomatoes. After digging, give a dressing of basic slag 10 cwt. to the acre. Have all finished not later than end of February.

"About the middle of May, if the ground is dry, dress with sulphate of potash 1 hundredweight and sulphate of iron, ground fine, ¼ hundredweight to the acre, then go over all with a hoe and chop down all weeds and level all hollows; do not rake. At each end of each row, where it is intended to plant the tomatoes, drive in a pointed stake of 2 by 4 in. broadway to the row, at a slight angle away. The stake should enter the ground 2 ft. and stand out 1 ft. 9 in. Then in direct line with the stakes, at intervals of 10 ft. drive in

studding boards ¾ inch × 2 in. × 2 ft. 6 in. long, to stand out of ground 1 ft. 9 in. The narrow way of the board should be in the line of the row. Now fix 16s gauge galvanized wire to the stake at one end, and draw tight and fix to stake at the other end. Fix wire to top of stakes by small wire staple. This should all be done before the plants are set out.

“During the last week in May and first week in June, the plants should be set out. Water well in the frame, then gently pull the plants and place as many upright in a basket as it will hold. Drop about twenty at 18 in. apart; then one person with a small, thin graft, or a garden trowel, should insert it about 4 in. into the ground at an angle, and press upwards, slightly raising the soil without disturbing it. A second person should insert the damp roots of the plant in the nick and tuck them carefully to the bottom, into the damp soil; remove the tool gently and press the soil firmly on to the plant with the heel. Do not water. I have tried many ways of planting tomatoes in the fields, and this I found to be the best method where large numbers have to be planted. Where only a small quantity are being handled it is best to grow them in strawberry baskets or pots, and put the plants out with the roots undisturbed.

“In a week or two, if the weather is genial, growth will be observed, and then a dressing of nitrate of soda may be given, about 2 hundredweight to the acre. It should be crushed fine and mixed with three times its bulk of dry earth or ashes. At the end of June the plants should be thoroughly sprayed with strawsonite. After spraying, it will be time to go over the plants, and remove all the side shoots, keeping the plants to one stem only. When the plants have grown long enough to reach 6 in. above the wire, they should be again trimmed of shoots and tied to the wire, resting the stem of the leaf on the wire before tying. Leave the tie rather slack for expansion of stem. After trimming and tying, spray again with strawsonite. This work should all be completed by the beginning of August, if the season is suitable to growth. If rain falls immediately after spraying, repeat it.

“The fruit should begin to show color by the middle of August, but this varies considerably with the season and the age of the plants when set out.

“As soon as the fruit shows pink, it should be gathered and taken to the packing shed. Do not gather the fruit green if it can be helped, but wait for a change of color. These gatherings should be continued at least twice a week so long as the fine weather continues. If the weather changes to wet after a long dry spell, it is very probable that many of the fruit will crack, and then it is advisable to gather the fruit green, if quite fully matured; this will save them from cracking. If the weather is cold and dull, the plants should be sprayed with Evans’ Aseptic Spray. This will not leave a stain on the fruit. After the second week in August, the plants may be topped, as this will help the fruits to swell, and fruit setting after this date will probably be useless. Keep the side shoots removed, and remove and shorten bottom leaves to let the sunlight into the plants. Remember this: plants allowed to grow close and crowded are much more liable to disease, and spraying does not thoroughly cover them; also plants with many shoots make less fruit, of a smaller size, and take longer to ripen; therefore anyone taking the trouble to raise plants and set them out, and neglecting them afterwards, is acting very foolishly.

“Continue to gather the fruits as ready, keeping a sharp look-out after the end of September for signs of frost. When this is feared, gather all the full-grown fruit on the plants whether green or not—they will ripen in-doors; but exercise some judgment, and do not gather fruit which is not full grown. This may color, but even if it does, it will be shrivelled and a bad color, and will spoil the market for better fruit. It is better to leave the immature fruit on the plants, as the frost may pass without doing any material damage, and there may be several weeks more of mild weather, which will give several more pickings of full-grown green fruit. I have picked in this way until the first week in November, some years.

“The fruit must be graded into ‘best smoothing,’ ‘small smooths,’—which description does not include very small fruits, but only those just too small for an even sample,—‘seconds,’ and ‘thirds.’ Seconds are good sound fruit, but include all the misshapen ones. Thirds are sound odds and ends—it is better to avoid the grade if possible. The fruit is sent to markets in baskets.

“Tomatoes may be obtained from the open in July by sowing the seed a month earlier, and growing on with more room in pots. If each plant has 9 in. square of space, and is properly attended to, it will have small fruits set when planted out, and ripe fruit can be gathered in July.

“_Ridge Cucumbers._ Prepare a good hot-bed as for tomato seed, and on the last day of April, sow the cucumber seed, two together, at 1½ in. apart all over the bed; cover with soil, press down, do not water, close up and cover with mats. The seed will be up in 2 or 3 days. Give water, plenty of light, but no air; cover at night. Have ready a mild hot-bed—the bed the lettuces were removed from, if forked over, will probably do. As soon as the rough leaves are showing, lift each pair of plants gently with a little soil and pot into large 60s, burying up to seed leaves. Water as required. Harden gradually by end of May, and plant out first week in June at 2 ft. apart in rows, and 4 ft. between the rows. A bed into which a heavy dressing of manure has been dug during the

winter will do very well. As soon as set out, the plants must be protected by some means, such as placing a flower-pot at night over each plant, or with paper cones pegged down. It is also advisable that hurdles covered with straw be run down every 3 or 4 rows to break the wind. If the plants are helped in this way for a week or two, they will repay it later on. After planting they should be watered, and this should be repeated if the weather continues dry. Before they begin to run, mulch all down each side of the rows with long straw stable manure. Fruit should be ready middle of July.

“For using the frames after the above plants have been removed, I recommend Frame Cucumbers. Melons would do equally well, but are rather more difficult to grow, and I advise cucumbers for a year or two until experienced. Make up a hot-bed precisely the same as for Ridge Cucumbers. Fill as many 60s pots as are needed half-full of prepared soil after covering the drainage hole with broken china. Put one seed of Telegraph Cucumber on the soil in each pot, fill half the remaining space with soil and press down with the bottom of a pot. The soil should be of a nice dampness when used, as the seeds are better unwatered; the pots, if new, should be soaked in water before use. Cover up close and keep mats on until seed is up, then only mat at night. Give no air, water with tepid water as required, shade from strong midday sun and keep interior of frame moist by dewing over early each morning. Give the plants room for the leaves to spread. As frames are emptied of the tomatoes and ridge cucumbers, without waiting for all of them, fork them over lightly and raise slightly in centre; on this mound put half a bushel of prepared soil, which should consist mainly of chopped sod with the grass removed, a little decayed manure, and a little finely sifted burnt earth or old mortar rubbish. Cover up close for a day or two for the sun to warm the soil, and then put two plants in the middle of the light, about 6 in. apart. Pinch out the centres, allowing only one shoot to grow from each plant. These should be taken from one plant upwards and the other downwards in the frame. Keep the growth thin; remove old leaves, one now and then; avoid overcrowding; if this seems likely, cut some of the shoots right out. Keep the frame moist, give plenty of tepid water, whiten about half the glass in the centre and splash the remainder. If these instructions are carried out, there will be an abundance of cucumbers to cut for market.

“The frame cucumbers are packed in flats, numbered according to size, but usually 3 to 4 doz. Put a little hay at the bottom, then cover with paper, put one layer of fruit very carefully on this and a sheet of paper over, a little more hay, another sheet of paper, then a layer of fruit and so on. Three layers generally fill the flat.

“Ridge cucumbers are generally sold by count or in bushels, but when grown especially fine may be sent in flats as above.”

FOOTNOTES:

[13] NOTE.—“Long” manure contains a good deal of litter that has not decayed, so that the manure does not break up into fine particles as “well-rotted” manure does.

Appendix IV.

The _Farm Journal_ for November, 1908, gives the following condensed list of the short courses offered by the various State Agricultural Colleges:

Specialized knowledge is the keynote of modern farming success. Why not give your boy or girl a chance to acquire some of this knowledge? In winter there will be a let-down of farm activity, and many of Our Folks could, if they tried, attend one of the short agricultural courses provided free by nearly every State. In many cases the only expenses are for board, books, etc., and the total cost of a few weeks’ course is thus very small. Many grown farmers attend these courses; there is no age or citizenship limit in most States.

For catalogues and full information write to any of the addresses given, mentioning this book. For instance, if you live in Alabama, direct your letter as follows: “J. F. Duggar, Alabama State Agricultural College, Auburn, Ala.”

Alabama. J. F. Duggar, Auburn: Offers a nine-month course in agriculture, and a two-year course.

Arizona. R. W. Clothier, Tucson: Offers a two-year course in irrigation, engineering, farm management, dairying and vegetable gardening, designed especially to equip students for farming under Arizona conditions.

Arkansas. John N. Tillman, Fayetteville: Short winter course in agriculture begins first Monday in January, lasting two weeks.

California. E. J. Wickson, Berkeley: Five different short courses covering special branches of farming. Write for particulars.

Colorado. B. O. Aylesworth, Fort Collins: A short practical course in agriculture and domestic science is offered by this institution.

Connecticut. C. L. Beach, Storrs: Dairy and creamery short course of twelve weeks. Pomology course of twelve weeks. Poultry course of six weeks. All courses open Tuesday, January 5th. A six-week forestry course begins November 2d.

Delaware. H. Hayward, Newark: Offers a six-week special course, from January 4th to February 15th; and a special “Farmers’ Week” from January 4th to 8th, inclusive.

Florida. Andrew Sledd, Gainesville: A two-year course specially adapted to the farmer’s boy. The instruction is of an applied nature with sufficient technical research to lead the student to question well the reasons for the various farm operations. College moved from Lake City to Gainesville.

Idaho. H. T. French, Moscow: Short courses are offered in dairying, extending one year; and farmers’ short courses in dairying and horticulture, extending six weeks, beginning about middle of January.

Illinois. Eugene Davenport, Urbana: Offers a two-week course in agriculture, and also in household science, beginning January 13th.

Indiana. J. N. Skinner, Lafayette: Four courses of eight weeks each, beginning January 18th, as follows: Agriculture and horticulture; animal husbandry; dairying; household economics.

Kansas. E. R. Nichols, Manhattan: Offers a ten-week farmers’ short course, beginning January 5th; a ten-week short course in dairying, beginning January 5th.

Kentucky. Clarence W. Mathews, Lexington: The college is now occupying its new building; offers a ten-week business course in agriculture, beginning January 4th. Tuition free to residents of the State.

Maine. W. D. Hurd, Orono: Offers an eight-week course in dairying, farm crops and horticulture; a special poultry course; and a “Farmers’ Week.”

Maryland. R. W. Silvester, College Park: Ten-week course in agriculture begins Tuesday, January 5th. Terms: Board, $40 for whole course; tuition free.

Massachusetts. J. A. Foord, Amherst: 1, dairy farming; 2, horticulture; 3, general agriculture; tuition free; begin first Wednesday in January and continue ten weeks. Bee culture; begins fourth Wednesday in May and continues two weeks.

Michigan. R. S. Shaw, East Lansing: Eight-week courses in general agriculture, horticulture, creamery and cheese making, beginning January 5th. No charge for tuition; board and lodging cheap.

Minnesota. E. W. Randall, University Farm, St. Paul: Farmers’ short course opens January 15th and continues four weeks. Dairy school opens November 16th and continues four weeks.

Nebraska. A. E. Davisson, Lincoln: The winter course opens January 4th and closes February 20th.

New Hampshire. Fred Rasmussen, Durham: A ten-week course in dairying begins January 5th.

New Jersey. E. B. Voorhees, New Brunswick: Offers three short courses, beginning December 1st and closing March 5th, as follows: General agriculture, dairy farming, market gardening and fruit growing.

North Carolina. C. L. Newman, West Raleigh: The seven-week course in agriculture begins January 11th; the one-week course in agriculture, January 4th.

North Dakota. J. H. Worst, Agricultural College P. O.: Winter short courses in cooking and sewing are offered for the young ladies. Also winter lecture courses for the men about farming, stock raising, etc.

New York. L. H. Bailey, Ithaca: Five winter courses, in general agriculture, in dairying, in poultry husbandry, in horticulture and in home economics. These courses begin December 8th, close February 24th. (See also New Jersey.)

Ohio. H. C. Price, Columbus: Offers a ten-week course in agriculture, and a similar course in dairying; both begin January 11th. Also a four-week course in domestic science, beginning February 1st.

Oklahoma. J. H. Connell, Stillwater: Several instructive short courses are offered. Write for particulars. Five hundred students attended these courses last year.

Pennsylvania. Alva Agee, State College P. O.: Five winter courses in agriculture, beginning December 1st and continuing for twelve weeks. Write for particulars.

Tennessee. H. A. Morgan, Knoxville: An excellent series of short courses are planned for the new year. Write for particulars.

Texas. S. E. Andrews, College Station P. O.: A two-year course in practical farm work. Send for details.

Utah. Registrar, Agricultural College, Logan: Offers winter courses in agriculture or forestry, domestic arts or mechanic arts, beginning January 5th.

Washington. E. E. Elliott, Pullman: Offers an eight-week course in dairying and a twenty-week course in agriculture.

Wisconsin. H. L. Russell, Madison: Offers a twelve-week dairy course, beginning November 4th; a general course (fourteen weeks), beginning December 5th, and a ten-day farmers' course, commencing February 2nd.

Wyoming. J. D. Towar, Laramie: The winter course of eight weeks begins January 4th.

Information regarding the short courses of several State colleges was not received in time for insertion here, and so such States are necessarily omitted from the foregoing list.

TRANSCRIBER'S NOTE

Illustrations in this eBook have been positioned between paragraphs.

Obvious typographical errors and punctuation errors have been corrected after careful comparison with other occurrences within the text and consultation of external sources.

Some hyphens in words have been silently removed, some added, when a predominant preference was found in the original book.

Except for those changes noted below, all misspellings in the text, and inconsistent or archaic usage, have been retained.

Pg 111: 'LEEK' replaced by 'LEEKS'. Pg 112: 'cultivaiton' replaced by 'cultivation'. Pg 272: 'profitble' replaced by 'profitable'. Pg 282: 'cions' replaced by 'scions'.

The Idea

The General Manager of a large Department Store sat in his study one night, puffing away at a big black cigar, with a real worried expression upon his face. Things were not right down at the Store.

Two months previous he had accepted the position as General Manager, and it had been gradually dawning upon him that he was waging a losing fight. The Store had an equipment and over-head based upon a total annual business of seven million dollars and was barely doing four.

For days he had been reviewing his Organization; the activities of his competitors, the possibilities of the City itself, the opportunities for the elimination of expense that might serve to reduce the over-head. It was a brain racking circle of thoughts and figures that seemed to lead nowhere but back to the starting point.

Sitting in his Study he tried his best to find a solution of the ever-increasing problem. Musing upon the situation aloud he said, “boiled down to a single sentence the problem seems to be this--how am I going to get the greatest amount of money in the shortest possible time?” The next thought was “to whom shall I look as an example of how that can be accomplished--who gets the greatest amount of money in the shortest possible time?” Suddenly he sat up as the thought struck him forcibly--“why, it’s the Circus that in the shortest space of time produces the greatest result.”

He couldn’t shake the idea and the next morning he had determined that he would seek out the General Manager of the largest Circus Company traveling the Country and ask him to what it was they attributed their success.

The General Manager was a man who, like most true Executives, acts on impulse, and he made up his mind that he would take the first train to where the Circus was showing and talk with its General Manager.

Fortunately the Circus was then located in a City about one hundred miles distant, and the General Manager made the trip.

In conference with the Circus man the next day he told him what he had in mind. “You folks,” he said, “it seems to me, more than any other business, get the greatest amount of money in the shortest possible time--how do you do it?”

The Circus man laughed. “It is more simple than you think,” he said. “We simply are most careful students of advertising; we plan and place our advertising so that ALL THE PEOPLE know when we shall arrive and how long we shall stay. We have found that some people read the newspapers, a great number; and some ride in Street Cars, quite a few; but that ALL PEOPLE who can come to our Circus use the great outdoors. Therefore, we spend eighty per cent. of the money we have for advertising, outdoors. By the use of outdoor publicity we get our greatest ‘punch.’ The Poster offers a use of color and size that dominates, and the eye cannot escape it. Then we so build our copy that ‘he who runs is compelled to read.’ We are specialists in evolving compelling copy--we are psychologists who have accurately gauged the public’s mind. We cater to the great masses, rich and poor alike. We must understand humanity in its entirety. So we use the Poster and painted signs--we tell our message in color and size and we reiterate it on every Highway and Byway until you cannot escape the message of the Circus and its appeal.”

The two men talked for a number of hours, and finally the General Manager said, “if your plan is a success for the Circus, why not for some other business? Is there any particular reason why your method can only be successful for a Circus Company?”

“No,” said the Circus man, “I think the method itself is sound and would, to a large degree, prove efficient for mostly any business, if as carefully planned as ours.”

The General Manager of the large Department Store, riding back to his City, thought over all that the Circus man had told him, and this one thought persisted in his mind--“Why not for the Department Store?”

Next day he laid plans for an Outdoor Advertising Campaign. He called in his Advertising Manager and a Representative of the Outdoor Advertising Company of his City, and said to them, “I want to place outdoor advertisements so that, no matter where you stand on any widely traveled avenue in this City at any point of circulation, you will be greeted by a dominant reminder of our Store. I am going to make this Institution _synonymous_ with _shopping_. I am going to so constantly reiterate that message, and I intend to do it in so attractive a way and with such compelling copy that the public will be unconsciously attracted to us in larger numbers than ever before. I am going to inaugurate within such changes as will make OURS the finest place to shop, rendering unquestionable service and having a ‘come again’ atmosphere about it; and I will look to the outdoor advertising that we will do to help build for us this prestige that, to my mind, is so necessary for an Institution such as ours.”

The General Manager was an enthusiast not given to half measures--one of those leaders of men who act instinctively and is nine-tenths right.

He said to the Advertising Manager, “I have set a figure of twenty thousand dollars as my limit for this Outdoor Campaign, and I want you to buy the most dominant Outdoor Display that was ever planned in this City. I want to go over every bit of the copy with you before it is finally executed, and I want the copy changed every month with a complete re-arrangement of both color scheme and message. I want to make, as I stated before, _our Institution synonymous with shopping_.”

Seven years have gone by, and the General Manager is President of his Company, which is now doing some twelve million dollars’ worth of business yearly.

No, the increase of eight million dollars in their business is not due entirely to this wonderful Outdoor Campaign that was put forth. The untiring energy of the General Manager, his far-sightedness and ability in re-organizing his Institution, have all gone to make this Department Store the wonderful business it is. It is significant that today his Company is still spending eighteen thousand dollars per year for Outdoor Advertising.

The General Manager said to me the other day, “I believe in our Outdoor Advertising because I have proven its value. It tells my message _to all the people_: To the Foreigners and the Illiterates who cannot read the newspapers and have money to spend, and who can absorb a simple message told to them, pictorially and in large size and color--to the _school girl who is the mother of tomorrow_, and to the busy man who rides in his motor car to and from his factory and glances only occasionally at his newspaper.

“Mind you I hold no brief for Outdoor Advertising alone--I am a consistant user of newspaper space, probably the largest in this City today, but I attribute the first growth and stimulus of our business to the wide-spreading use I made of Outdoor Publicity.

“I do not believe that a Department Store can be successfully advertised by Outdoor Advertising alone, any more than I believe it can be most successfully advertised by newspaper advertising alone. I believe that a Department Store is best served by a judicious combination of both.”

This General Manager, as I said before, is President of his Institution today, one of the wisest men in the Department Store field in America.

And the best part of this Story is that it is _absolutely true_ and was told to the writer almost as set down.

NOTE

Our organization has the advantage of a merchandising experience covering a period of 40 years. We have served clients who have grown from infant industry to corporations doing fifty million dollars or more per year.

We have carefully collected and compiled sales and advertising data, a great deal of which is applicable to all business.

We have a sane, workable plan we should like to present to you.

Registered by the Postmaster-General for transmission through the post as a book. 1922

TO SUSIE

WHO LOVES ALL LIVING THINGS

[Illustration: “_A soft mauve mist_”--_White Cedar_]

THE WILDERNESS

Once, long ago, part of it was garden, and the clearing between the redgums and ironbarks was planted with fruit trees and roses; but the gardener went the way of all flesh, and those who came after him did not have the same love for the garden. Now the bush has reclaimed its own, and roses and fruit trees are half hidden by the tangle of wild things which have gradually crept over them. Each spring the fruit blossoms still shine out on the unpruned trees--all the lovelier for their disorder--and mingle with the gold of the wattles; myriads of undisturbed bulbs--ixias, freesias and sparaxis--send up their blooms among the long swordgrass, outrivalling the blooms in my own well-worked garden beds.

Lovely as the bush-girt garden must have been in its orderly days, it now holds joys undreamed of then. With the creeping return of the wattles and tecoma, the mistletoe and hardenbergia, have come back many of the shy living creatures which had been driven away by the gardening; and now that there is no more digging and planting to disturb them they live as happily as if they were a hundred miles away from men and houses, instead of in the midst of a popular suburb.

Fortunately the wilderness is not a desirable building allotment. The little creek which bisects it makes the site too damp for a house, and so no ruthless builder casts a speculative eye upon it. But the creek is an attraction for numberless creatures--birds, butterflies, bandicoots, frogs, and myriads of those tiny living things which we carelessly group together as “wogs.”

To the entomologist the wilderness would be a perfect paradise, for it is the breeding place of many things--not all loved by the ordinary mortal. Many species of ants have their homes down there; and paper wasps love to make their wonderful many-celled nests on the old fruit trees. Cicads crawl out of the soil each spring and creep up the gum trunks to shed their husks before they wing out to fill the wilderness with their humming song.

[Illustration: _The Paper Wasp’s many-celled nest_]

Trapdoor spiders lurk down near the creek, and many of the web-making ones spin their light gossamer from branch to branch. Antlions have their little pits to trap the unwary, and dragonflies flitter restlessly over the water.

[Illustration: _The Dragonfly_]

Most interesting of all to the non-entomological mind are the butterflies. Down in that tangle of trees, grass and ferns are to be found the larvæ and pupæ of many butterflies which in time develop into living jewels. On dull days, and in late afternoons, the funny little caterpillars of the small blue butterflies march out in a solemn procession to feed on the thick fleshy leaves of the mistletoe which grows so lavishly throughout the wilderness. Later they wander down from the mistletoe clumps and enter the nests of the stodgy brown sugar-ants to pupate. It is strange to think that these gay, blue creatures rise from among such queer bed-fellows to flutter round my garden flowers. For in time all the full-fledged butterflies leave the denseness of the wilderness to hover over my beds of zinnias and larkspurs, outshining the brightest blossoms. Most gorgeous, I think, are the vivid turquoise blue and black ones called Papilio, which attract me by their name as much as by their beauty. Very lovely, also, are the big brown butterflies with the eyes on their wings, while there is a distinct fascination about the little “skippers” which vary in shade from cream to brown, and which are known by their different flight.

[Illustration: _The vivid turquoise blue and black Papilio_]

The man who made the wilderness garden must have had a true Australian love, for even in the cultivated beds he planted native things. Along the upper fence he put a row of silver wattles; most of them are long since dead, and their bare branches serve as supports for the wandering tecoma and the red-berried solanum. But their children are scattered throughout the wilderness, making a silver-grey mist, which in spring gives way to a golden blaze. They are in every stage of growth, and as the older trees die off there are always new ones coming to perfection.

Pittosporums, too, he planted, which fill the mild spring evenings with their heavy sweetness; and many Christmas-bushes. These enjoy the wealth of food which comes from all the leaf-mould and decay, and at Christmas time each year their rosy branches glow like beacons through the green glade.

[Illustration: _The formal cypress shape of the Native Cherry_]

Close by the creek grows one of the loveliest of the wild trees, the native cherry (_Exocarpus cupressiformis_). There is quite an old-world charm in its formal cypress shape, which seems to reprove the irregular gums and she-oaks; and the gold-green of its tender tips stands out in lovely contrast against the blue-green and silver-grey of the other trees. When the setting sun catches it through the taller tree trunks it glows like a fairy Christmas tree, and one can picture the little folk dancing round it in a ring. It grows at the very edge of the once cultivated plot, and I think the planner of that garden must have stopped short just there in order to save the lovely thing. Beyond all this is natural bush, with tall spotted pink orchids pushing through in the spring-time, under the golden pultenea and dillwynia, and in summer a white cloud of snowbush.

There is a peculiar fascination in the mixing of wild and tame in that wilderness. The white shasta daisies growing higher than my head in their effort to see the sun through the too protective red-shooted gums; the orange-flowered mistletoe drooping from the tall ironbark to touch the appletree below, seem to me symbolical of that mixing which should come so naturally between things--and people--of this land and of the old.

[Illustration: _The orange-flowered Mistletoe_]

Of all the trees in the wilderness there is none which so completely satisfies me as the white cedar (_Melia composita_). It grows on the upper edge, close to my verandah, and I know it through every varying phase. I never can decide in which season I love it most. It is one of our few deciduous trees, and after its pale golden leaves have dropped it is bare for a short space. Then a soft mauve mist breaks over it, and it is covered with a myriad lilac-coloured, lilac-scented blossoms, which pour their perfume lavishly into the world. I think it is a much lovelier tree than the lilac, for, while its colour is not so deep, the flowers grow in much lighter, more feathery fashion, and the whole effect is that of a mass of misty lace. While the blossoms are at their sweetest the little green leaf-tips have been bursting through. They grow swiftly from slender fingers to waving tassels, and then to open fans, and by the time the flowers are finished the tree is dressed in a beautiful fern-like foliage of glossy green. Nor do its charms end here. The flowers have left behind them hundreds of small green fruits, which grow and ripen, and by the time the autumn comes again and the leaves begin to fall they are ready to provide a beautiful feast for the birds. And so comes the white cedar’s crowning charm.

A tree without birds in its branches is like a room without books on its shelves--the birds are the crowning charm. The poet knew that when he wrote ecstatically of--

A tree that may in summer wear A nest of robins in her hair.

My white cedar does not wear any nest in her hair, but each autumn her charm is enhanced by the beautiful green oriole in her branches.

In autumn the fat green berries have grown golden and juicy, and the oriole comes to feast upon them. He really has no right to be so near Sydney nowadays, for he is one of the larger birds, which have been driven back by the advance of the city; but somehow or other, in the mysterious bird way, he learned of my white cedar, and each year he comes to spend a month or so in the wilderness, feasting on the berries, and in between meals filling the autumn day with his lovely, clear ringing song. He is one of the lucky birds, whose voice matches his form in beauty. For he is, indeed, a beautiful bird, with his olive green back, creamy breast streaked with black, and bright red eye and bill. He is big enough, too, to show up in the landscape, and towards the end of his stay, when the cedar is nearly leafless, he makes a lovely note of colour on the bare branches against the blue sky.

[Illustration: _The beautiful green Oriole_]

But he has rivals in the wilderness--many rivals, both in voice and appearance. I am not sure that the blue jays are not more lovely to look at. Their silvery bodies and black faces are not so gay, of course, but they are slim and slender, and they float through the tree-tops with wonderful grace. They come in flocks to the wilderness during the winter, and it is a joy to watch them swaying in the tree-tops, then darting suddenly down to catch an insect on the wing, and up again to their swinging perch. Pity 'tis their voice has no beauty, but is just a querulous squawking note.

Handsome creatures, too, are the dollar-birds which visit the wilderness every year and drift amongst the tall tree-tops, displaying the silvery dollars on their wings against a blue-and-brown background. But their voices!--a small boy compared them to a lot of mad frogs, and the description is not inapt. Fortunately for our ears these harsh-voiced birds are short-stayed visitors, but many of the birds that linger in the wilderness are true singers.

As I write the air is filled with the glorious song of the butcher-birds, which stay with us all through the late summer and autumn and sometimes come in the spring. I have heard all the old-world songbirds--the nightingale and the lark, the blackbird and the thrush--heard and loved them all. But for sheer beauty and volume I know no bird whose voice compares with the butcher-bird's, and I think it is a sin that he should be so named.

It is not his habit of making an occasional meal from a small bird that has given the butcher-bird his name, for many birds have the same habit. It is his peculiar custom of storing his food that has gained him the reputation of keeping a "butcher's shop." Most birds kill an insect as they need it and either eat it or carry it off to their nestlings. The butcher-bird thriftily makes a small collection of insects and lays them in a row. I have seen him lay a huge brown grasshopper and a slim praying mantis side by side on my garden rail, and then fly off and hang another grasshopper in a slender fork of a wattle.

Gould, in his famous work, pictures the butcher-bird with a blue wren hanging from a fork in the tree beside him, a picture which naturally ruined the bird's reputation. I am happy to say I have never seen that horrid tragedy, and from personal observation I think that insects are a much more usual part of his diet than are little birds. At any rate, with such a beautiful voice he deserves the benefit of the doubt. I hope it is not characteristic of us that in naming him we should have overlooked his rare beauty and pounced on his little weakness, though I cannot help thinking that in more aesthetic lands he would have had a name more suited to his beautiful song.

[Illustration: _Our best autumn singer--the Butcher-bird_]

The butcher-bird--since I must call him so--is our best autumn singer, but in the spring his place is taken by the grey thrush. He is next, I think, on the list of our songbirds, and his sweet ringing call holds all the freshness and joy of spring. He is such a darling bird to have about the place. He perches on the redgum or the wattles, which stand in line with the white cedar, and he looks down at me with his big round eye in the friendliest fashion. So graceful he is, too, and so elegant in his neat grey coat, that I always place him in my mind amongst the beautiful birds, though some might call him plain.

Whilst you might dispute the grey thrush's claim to beauty, no one can deny that of two other of my songbirds, the two thickheads, or thunderbirds, as they are sometimes called, because they burst into song after a clap of thunder or any sudden noise. The

yellow-breasted one is very gorgeous, with his white throat and black face; but the rufous-breasted one is handsome, too. Sometimes he breaks into a whip-like note, which has earned him the name of “ring-coachie” amongst small boys. Once, on a rare occasion, the coachwhip bird himself sent his call up from the little creek. As every one knows, the coachwhip bird is a shy, furtive creature, rarely seen by anyone but real bird observers, though his voice is common enough in the gullies. We are nearly a mile away from the gully where he lives, and he must have crept up through the intervening gardens to have a look at the wilderness. Just once he came, but though I have looked and listened I have had no sign or sound of him since.

A very familiar birdcall in the wilderness is that of the cuckoo--or I should say “calls of the cuckoos,” for there are five different sorts, with five different calls, amongst our regular visitors. Of course, none of them says “cuckoo.” Once I used to cherish a secret feeling of resentment that we should have so many true cuckoos in Australia without one possessing the call associated with the name. But after four English Mays, in which the cuckoo calls all day, I thanked fate that I lived in a land where the cuckoo did not say “cuckoo” from dawn till long after dark. For a more monotonous birdcall I have never known. Our big scrub-cuckoo, the Koel, is nearest to it in monotony; but the five that visit the wilderness have quite different songs. True, the fantail and the two little bronze cuckoos have merely plaintive Whistles, but the big pallid cuckoo has a fine ringing song right up the scale, and the square-tailed calls over and over a distinct phrase, in a higher key each time.

[Illustration: _A simple creature_]

The shrike-tit, that gorgeous yellow-and-black fellow with the black crest, is one of the loveliest birds amongst our regular visitors, and one of my favourites, for he has such an unsuspicious nature. His long drawn out, rather plaintive note is very easy to imitate, and we can always bring him down to us by repeating the call. Again and again I have seen the simple creature hurrying through the wilderness in response to a human whistle, and flying wonderingly from tree to tree in search of his calling rival. Sometimes he comes within a few feet of us, dancing with rage and chattering angrily at the hidden intruder, before he discovers the fraud and flies off in disgust.

[Illustration: _The attractive Lalage_]

A visitor which has a particular attraction for me is the Lalage. I like his smart coat of black and white and grey, and I like his sweet trilling song, but what I like most is his name--his scientific name. For he is one of the few birds whose scientific name is preferable to the vernacular or the colloquial; _Lalage tricolor_ is far prettier and easier to say than “White-shouldered caterpillar-eater,” or the stupid “peewee lark.” Other birds that visit us occasionally are parrots. I have noticed five kinds--Rosellas, Mountain Lowrie, Blue Mountain parrots, and two little green lorikeets. They have always come when the eucalypts are in flower, and I love to see their gay bodies flashing against the creamy blossoms as they feed noisily on the honey. If only people would realize how much life and colour they bring to their gardens by retaining food-giving trees, I am sure they would not be so ruthless about cutting down trees to make way for roses and dahlias. No bed of flowers could be so soul-satisfying as the sight of a flock of parrakeets feeding in the honey-laden blossoms of a flower-covered bloodwood.

Just as gay as the parrots, though very, very much smaller, is the red-headed honey-eater, or bloodbird, as he is more familiarly known. He is also a honey lover, and visits us when the trees are in blossom. His bright red-and-black coat makes a vivid spot of colour, and his pretty little song adds to the general harmony.

The profusion of mistletoe in the wilderness brings us the mistletoe-bird. Few people really know this tiny steel-blue crimson-breasted fellow, or his plain grey little wife. Yet his single whistle, like that of a small boy who has just learned to whistle through his teeth, is one of the commonest sounds in the bush, and the mated birds call continuously when feeding in different clumps, as if they feared to lose touch with one another. One of the great charms of a wattle, which till lately stood beside my verandah, was that its leafy tops were beloved by the mistletoe-bird. When he had taken his fill of the luscious and viscid berries which dropped from the redgum by the gate, he would retire to the wattle, hide himself amongst the grey-green foliage, and pour out an ecstasy of song in the tiniest of voices. Many birds, even to so bold a fellow as the butcher-bird, have this habit of hiding amongst the thickest leaves and soliloquizing, but none has a more impassioned utterance than the little mistletoe-bird, though none has so slender a song.

Sometimes we find their nest, one of the most wonderfully built of all birds’ nests. It is woven from fine plant fibres and silky seeds, and is hung from a slender twig, with a little entrance at the side; it is very like a little purse of felt, save that it is not so harsh to the touch as felt.

[Illustration: _Spine-billed Honeyeater_]

One more of our visitors I must mention, and that is the native canary, which comes each year, builds his little domed nest in a sapling, and fills the air with his sweet song. Then there are the everyday birds, the dear, familiar things which are with us all the year round. Every gardener knows them--blue wrens and tits, jacky winters and yellow robins, redheads and spinebills, peewees and kookaburras--they are the usual inhabitants of our suburban gardens, and dear to us all because of their friendly, fearless ways. Other birds come and go, but they stay with us all the time, building and breeding in the wilderness each spring. In the two years that I have known this wild patch I have counted seventy-two species of birds passing through. Some, as I have said, are there all the time; some come at certain seasons, sing for a space amongst the tree-tops, feed for a week or so on the berries and blossoms, then pass on to other feeding grounds, while others stay just for an hour, glad of a safe and sheltered resting-place on their long, mysterious journeys to and fro across the land.

[Illustration: _So tame and friendly--Blue Wrens_]

Fascinating as the wilderness is by day, it is at night that one feels its deepest spell. Then all the strange elusive creatures come out from their hiding places, and go about their business in the tree-tops or down under the thick shrubs. One needs keen hearing to know the wilderness by night, for eyes alone are not much good.

I can never make up my mind which I love most--the birds that live all the year round in the wilderness, and are so tame and friendly that they come right up on to my verandah and sit and sing within a yard of my chair, or the visitors which bring the feeling of distant places with them, and carry my thoughts far, far away. But of one thing I am sure, and that is my gratitude to the man who left this little wild patch in the heart of the houses to be a sanctuary for all wild things. Noisy people passing by may think it is a mere empty patch of trees; but we who have sat silently on our verandah through the long still summer evenings and listened to the whisperings and stirrings, know that there is a distinct world of living things waking and moving down there in the shadows.

[Illustration: _Long-nosed Bandicoot_]

First of all there are the bandicoots, two kinds of them, amusingly named the long-nosed and the fat bandicoot. One stumbles over a few of their holes by day, but no other sign of them is there; yet at night out they come by the dozen. We hear them rustling through the long swordgrass, right up to the garden where occasionally--not often--they do considerable damage by rooting amongst my bulbs. Their queer little cough always betrays them, though I must admit they do not seem at all anxious about hiding their presence. It always gives me a distinct thrill of pleasure to hear that quaint little note just beside my verandah, and its wild touch is a happy contrast to the jazz music thumped out by my neighbour's pianola. More silent than the bandicoots, though no more stealthy, are the ring-tailed 'possums, of which there are quite a number in the wilderness. Last summer one built on the roof of our verandah, and every evening, as we sat having our coffee in the dusk, we used to hear his little patter across the flat roof. We could see him leap forth into a branch of the tall wattle which bent towards the verandah, then up and across to the taller redgum beyond, and away down into the heart of the wilderness. Sometimes when the hot summer nights have driven off sleep I have heard him in the dawn, scrambling back to bed, just as the birds have been waking up. I must confess that I felt very proud at having such a rare and distinguished lodger.

[Illustration: _The Big 'Possum_]

Occasionally we see the big 'possum. I am not quite sure where he lives, though I know two or three likely spots; but now and then he comes right out into the open, and we both see and hear him. One moonlight night he was feeding on the cedar berries not ten yards from the verandah, and even if his clawing and crunching of the berries had not betrayed him, he was quite visible as he hung on the swaying bough amongst the fern-like leaves, while every now and then as he moved I could see his big eyes shining brightly in the moonlight.

[Illustration: _Then there are Owls_]

Then there are owls--three or four sorts of them--which drift in absolute silence from place to place. On moonlit nights a sudden shadow floats on the ground before you, and if you look up quickly enough you will see a white form settling silently on a branch or post. If you keep very still and watch patiently you may see him dart down to catch some flying insect, or make a sudden swoop at a mouse in the grass below. How they see their prey is always one of the wonders of nature to me, but apparently they never miss. I like the names of my owls--the delicate owl, the masked owl and the Boobook owl--the last so named from his familiar double note "Boo-book."

The old mopoke, who for many years got the credit for the boo-book owl's note, lives in the wilderness, too. Like most of the nocturnal creatures, he likes the tall redgum which stands beside my gate, and he sits there for an hour at a time constantly uttering his soft mysterious note, "Oom, oom, oom." Sometimes he comes closer, on to the fence, or even on to the verandah post itself. In the daytime he sits silently for ages in what must be a most uncomfortable position, pretending to be a branch of the tree, but at night he gives himself away by his "Oom, oom, oom," for even the dullest human knows that trees don't say "Oom, oom, oom." Still, he is clever at catching his food, and the nocturnal insects find him as formidable as the owls.

Whenever we have a few days rain the little creek in the wilderness fills up, and then the frogs make high holiday. Most people will tell you that a frog croaks, and leave it at that. But, as a matter of fact, in proportion to their numbers, there is as great a variety in frog songs as in birds'. Once you have realized the differences you will wonder however you were so stupid as to think them all the same. There is the deep "Craw-craw, craw-craw" of the big green tree-frog, _Hyla coerulea_; the familiar chant, "Craw-awk, crawk, crok, crok," of the golden tree-frog, _Hyla aurea_--I give you their scientific names because they are so charming--the slow "Kuk-kuk-kuk," and the high, piping, hurried "Cree-cree-cree-cree" of two other _Hylas_. Then there is the insect-like "Crikik, crikik" of the little brown _Crinia_, and the harsher "creek" of the tiny brown toadlet. The two frogs which rejoice in the name of _Limnodynastes_, "King of the pool," have quite different notes. One has an explosive "Toc, toc, toc," like a machine gun, and the other calls "Kuk-kuk-kuk-kuk." Then the funny old burrowing frog calls softly "Oo-oo-oo-oo," and sounds more like a bird than a frog.

On fine mornings after rain, when the croakings overnight have told me what is afoot, I visit the little creek to see which of the frogs have spawned. A patch of froth, like soapsuds, with tiny spheres of black and white embedded in it, is the egg-mass of one or other of the two species of _Limnodynastes_. Two kinds of eggs are neatly arranged in cylindrical bunches round the submerged roots and grasses. Each egg is surrounded by a sphere of clear jelly, and a thin gelatinous matrix envelopes all the eggs. Those of _Crinia_ are black and white, those of _Hyla ewingi_ brown and cream. Floating on the surface, as if peppered over it, are the brown-and-white eggs of _Hyla coerulea_; while hidden under the debris round the edges of the water I find the much larger eggs of the little _Pseudophryne_, twenty to a nest, with the gaily orange-marked mother toadlet in attendance.

[Illustration: _A balloon almost as big as the frog itself_]

All are amusing, as frogs have ever been since the days of Aesop and Aristophanes; but there is none so amusing as the big green tree-frog, _Hyla coerulea_. He is the one that makes the great frog concert in moist places, and many a bad sleeper has cursed him for croaking on all through the hours of darkness. But once you have seen one of these frog gatherings you can never feel quite the same about their chorus. Amusement will temper your irritation. They come from all round the neighbourhood to the meeting place, and in the dusk you may even trip over the large green frogs hopping along the footpath on their way from neighbouring gardens. Often the gathering numbers hundreds, and they sit about the edge of the pond, in the grass, and on the stones, chanting loudly. And at each deep note a great balloon swells out in front of the throat, a balloon almost as big as the frog itself, going up and down, up and down, as each deep note goes out and the breath comes back for the next boom. I know of nothing in the whole bush quite so ludicrous as a frogs' party, and I must confess that the knowledge that so few people have attended one adds to its interest. There is a rare satisfaction in being on intimate terms with the really shy, strange, wild creatures. If you would share my pleasure all you need do is to keep a little wild patch of bush near your home. For wherever there is sanctuary the shy bush things will come and make their homes beside you.

THE PATH OF THE COSSACK

An ancient way leads across northern Asia to the Chinese borderland. The steel of the great Siberian Railroad harnesses now the stretch which mounts the Urals, pierces the steppes, winds through the Altai foothills, and by cyclopean cuts and tunnels girdles Lake Baikal. From Verhneudinsk southward, it has remained as an ancient post-road leading through the Trans-Baikal highlands to the frontier garrison town of Kiahta. Over the Mongolian border at Maimachen, it has narrowed into a camel-trail threading the barren hills to the encampment of the Tatar hordes at holy Urga. Thence it strikes across the sandy wastes of Gobi, and passes the ramparts of the Great Wall of China, on its way toward Peking and the Pacific.

Through five centuries this road has been building. Cossacks blazed its way; musketoon-armed Strelitz, adventuring traders, convicts condemned for sins or sincerity, land-seeking peasants, exiled dissenters, voyaging officials--all have trampled it. Hiving workmen under far-brought engineers have pushed the rails onward, bridging the chasms and heaping the defiles. Following it eastward, unpeopled wastes have been sown to homesteads, hamlets have grown into cities. To the very gateway of China it has led the Muscovite. It is the path of Slavic advance.

The way scarcely passed Novgorod in the early sixteenth century when the great family of the Stroganovs, a "kindred in Moscovie called the sonnes of Anika living neare the Castle of Saint Michael the Archangel," began the fur-trade with the Samoied tribesmen from Siberia, who paddled down the Wichida River to barter peltries with the Russians. The prudent merchant Anika, looking to a more permanent source for those valued furs than the irregular visits of the aborigines, planned to anticipate his brother traders in their purchases. He sent east with a band of returning Samoieds some of his own henchmen carrying, for traffic with the inhabitants, "divers base merchandise, as small bels, and other like Dutch small wares." The agents returned to report what impressed them most. There were no cities. The Samoieds were "lothsome in feeding,"--even a Russian frontiersman might shrink from the cud of a reindeer's stomach as food,--and knew neither corn nor bread. They were cunning archers, whose arrows were headed with sharpened stones and fishbones. They were clad in skins, wearing in summer the furry side outward and in winter inward. They willingly gave sable-skins for Dutch bells.

A series of trading expeditions began, which made the Stroganovs so enormously wealthy that "the kindred of Anika knew no ends of their goods." Indeed, they gained so much by this exploitation that they began to fear the application by the Czar's agent of a monetary test of patriotism. So, by a stroke of finance not unknown in modern days, there was arranged the Russian equivalent for carrying five thousand shares of Metropolitan. A block of small wares for the account of the Czar's brother-in-law, Boris, was added to the stock in an especially important expedition among the Samoieds and Ostiaks. The adventurers got far inland. They saw men riding on elks, and sledges drawn by dogs. They returned with wonderful tales of marksmanship, and, more important, brought back enough furs to give Boris a dividend, in gratitude for which he secured to the Stroganovs the grant of an enormous tract of land along the Kama River and a monopoly of the trade with the aborigines.

The Stroganovs grew and thrived. They scattered trading-posts and factories along the river-highways and sent many parties into the interior to barter. In the half-century following old Anika's expedition, they had carried the Slavic way to the Urals.

In the summer of 1578, when Maxim Stroganov was ruling over the family estates along the Kama, one Yermak, heading a fugitive band of Cossacks, tattered and spent, with dented armor and drooping ponies, straggled into camp and offered service. With great delicacy Maxim forbore pressing too closely his inquiry into their antecedents. It might have wounded Yermak's susceptibilities to avow that his chief lieutenant, Ivan Koltso, was under sentence of death for capturing and sacking a town of the Nogoy, and that the immediate cause of his advent was an army of Imperial Strelitz, which had driven his band from the Volga District for piracy and highway robbery.

The situation on the far side of the Urals, where the skin-hunting tribes had been conquered by a roving horde of Tatars under Kutchum Khan, was at this time interfering sadly with the Stroganovs' fur business. Eight hundred Cossacks, furthermore, of shady character and urgent needs were undesirable neighbors. So the prudent Maxim, not particularly solicitous as to which of the two might be eliminated, offered Yermak a supply of new muskets if he would go away and fight the Tatars. They were not pleasant people for the Cossacks to meet, these former masters of Moscow. But behind were the soldiers of Ivan the Terrible. With a possible conquest before, and the Strelitz behind, Yermak gladly chose to invade the Tatar territory, which is now western Siberia.

Up the Chusovaya River the little expedition started in 1579, damming the stream with sails to get the boats across its shallows. Penetrating far into the mountains, the band reached a point where a portage could be made across the Ural water-shed. Then they headed down the Tura River into Siberia. Here the invaders met the first army of the Tatars under Prince Yepancha, and with small loss drove them back. Yermak made his winter camp on the site of the present city of Tiumen.

Next year the advance began once more. The Khan of the Tatars, Kutchum, was alive to the seriousness of the incursion, and prepared to ambush the Cossack flotilla as it descended the Tura. At a chosen spot chains were stretched across the stream, and bowmen were stationed on the banks to await the coming of Yermak and overwhelm with arrows his impeded forces. The Tatar sentries above the ambuscade signaled the coming of the boats; all eyes were turned intently upstream. Then Yermak's soldiers fell upon them from the rear, to their total surprise and his complete victory. Straw-stuffed figures in Cossack garments had come down in the boats; the men themselves had made a land-circuit and had struck the enemy unprepared.

In defense of his threatened capital, Sibir, the old Khan rallied once more. He assembled a great army, thirty times that of the Cossacks. For the invaders, however, retreat was more perilous than advance. Yermak went on, and in a great fight on the banks of the Irtish, again prevailed. With his forces reduced by battle and disease to some three hundred effectives, he entered Sibir on October 25, 1581. A few days later the Ostiak tribes, glad to escape their Koran-coercing masters, proffered their allegiance, and the Cossack saddle was on Siberia.

But how precarious was their seat! Southward were the myriads of the unconquered hordes of Tatary; only one of the score of their khans had been vanquished. As thistledown is blown before the wind, so could Yermak's oft-decimated band have been swept away had once the march of the Mongols' main division turned northward. Girding him round were the self-submitting Ostiaks, loyal for the moment to those who had won them freedom from the old proselyting overlord, but not long to be relied upon once the weight of Cossack tribute--the fur-yassak--began to be felt.

But what the Tatar hordes had not, what the Ostiak hunters had not, the three hundred Cossacks had--a man. This man, starting his march as the hunted captain of a band of outlaws, could conquer half a continent. Then over the heads of his employers, the mighty family of Stroganov, over the heads of governors of provinces, of boyars, of ministers to the throne, he could send by his outlaw lieutenant, Ivan Koltso, loftily, imperially, as a prince to a king, his offer of the realm of Siberia to Ivan Vasilevich.

Ivan the Terrible, Czar of all the Russias, he who had blinded the architect of St. Basil, lest he plan a second masterpiece; he who had tortured and slain a son, hated less for his intrigues than for his unroyal weakness, responded imperially. Over the long versts Ivan's courier carried to Yermak a pardon, confirmation as ruler of the newly-won realm and the Czar's own mantle, an honor accorded only to the greatest, the boyars of Muscovy. Following the messenger eastward there plodded three hundred musket-armed Strelitz to bear aid to the Cossack garrison. Sorely now were these reinforcements needed, for the Ostiak tribes flamed into rebellion against King Stork. With Kutchum's Tatars, they returned to the attack and besieged Sibir. Once again, though hemmed about by the multitude of his enemies, the valor of Yermak saved his cause. In a totally unexpected sally, in June, 1584, the Tatar camp was surprised, a great number massacred, and the besiegers scattered.

The whole country, however, save only the city of Sibir, was still in arms. Engagements between small parties were constant. Ivan Koltso, striving to open a way for a trader's caravan, fell with his fifty, cut down to the last man. Yermak, marching out to avenge him, was himself surprised near the Irtish. With Ulysses-like adroitness, he and two followers escaped the massacre and reached the river-bank, where a small skiff promised safety. Leaping last for the boat, Yermak fell short, and, weighted with his armor, sank in the river that he had given to Russia. The two Cossack soldiers alone floated down to their comrades.

One hundred and fifty, all that were left of them, started their long homeward retreat. Far from Sibir, they met a hundred armed men sent by the Czar. Great was the spirit, not unworthy of the dead leader, that turned them back, to march to a site twelve miles from Sibir, where they built their own town, now the city of Tobolsk.

In the years that followed, their nomad enemies drifted south, leaving those behind who cared not for their old khan's quarrels. The phlegmatic Ostiaks returned to their hunting and to their feasts of uncooked fox-entrails. The long fight had rolled past, leaving the Slavic way undisputed to the Irtish.

Well it was, for no more of the Strelitz marched to the aid of the garrisons. Russia was in the throes of civil war and invasion,--the long-remembered "Smutnoe Vremya," time of troubles. Boris Godunov, once favorite of Ivan the Terrible, became the real ruler in the reign of the weak Feodor. On the death of this prince, with the heir-apparent Dimitri suspiciously slain, he had mounted the empty throne, and a pretender, claiming to be Dimitri miraculously escaped, had risen up in Poland, gained the support of the king, and marched against Boris. Though the Polish army was routed, Boris succumbed shortly after to a poison-hastened demise.

[Illustration: YERMAK'S EXPEDITION TO SIBIR ATTACKED BY THE TATARS (From a painting by Surikova)]

Dimitri attacked the new czar, captured Moscow, and was crowned in the Kremlin by the Poles. A revolution followed within a year, in which the pseudo-Dimitri was slain. Meanwhile the Poles were devastating Russia more cruelly than had the old Tatar conquerors. At length Minim the butcher of Novgorod led a popular revolt, which in 1613 carried to the throne Michael, the first of the Romanovs.

Through all these years, despite the fact that anarchy and chaos rioted over Muscovy, despite the fact that no troops came to aid in the advance, the Cossacks still pressed their way, contested by the scattered bands of Tatars, and farther on by the Buriats, the Yakuts, the Koriats. After these fighters and conquerors came the traders and colonists, with their families, following along the road that had been won. The valleys of the great Siberian rivers, which so short a time before had been the grazing-grounds of the Tatars, became dotted now with the farms of the new-come settlers. The advance guards of the fur-traders, with blockhouses guarding the portages, and clustering wooden huts and churches, pushed south and east as far as Kuznetz, at the head of navigation on the River Tom, and to the foot of the Altai Mountains. North and east the trade-route was advanced to the Yenesei, twenty-two hundred miles inland. As many as sixty-eight hundred sables went back to Russia in 1640, together with great quantities of fox, ermine, and squirrel-skins.

The quaint volumes of "Purchas his Pilgrimes," published in 1625, tell of some of the early explorations. A band of Cossacks dared the upper Yenesei, which "hath high mountains to the east, among which are some that cast out fire and brimstone." They made friends of the cave-dwelling Tunguses in this region, who were themselves stirred to explore, and went on far eastward to another river, less than the Yenesei but as rapid. By faster running the Tunguses caught some of the inhabitants, who pointed across the river and said "Om! Om!" The old chronicler diligently records the speculation as to what "Om! Om!" could mean. Some thought that it signified thunder, others held it a warning that the great beyond teemed with devils. These unfortunate slow-running natives died, "probably of fright," when the Tunguses, in a spirit as naïvely unfeeling as if they were collecting curios, were taking them back to be exhibited to their friends the Cossacks. How far these Tunguses had pierced cannot be told. In one of the dialects of the Yakuts who live beyond Baikal, "ta-oom" or "tanak-hoom" means "greetings." Had the Tunguses and the Cossacks who followed them arrived at the Yakuts' country? Or was the river on which passed "ships with sails" and beyond which was heard the booming of brazen bells the Amur? Were those the junks and temple-gongs of the Manchus? _Ni snaia_,--who knows?

In 1637 the Cossacks reached and established themselves in Yakutsk. In 1639 by the far northern route they pierced to the Sea of Okhotsk. In 1644 a party reached the delta of the Kalyma, and curiously speculated upon the mammoth tusks which they found. In 1648, on the Cellinga River beyond Lake Baikal they built Fort Verhneudinsk. Had their tide of conquest now rolled southward, up the Cellinga Valley, the Russian Eagles might to-day be flying over Peking. Only the Kentai Mountains were between them and prostrate Mongolia, enfeebled by the internecine warfare of her rival khans. From Mongolia, the road, worn by so many conquerors of old, leads fair and clear to the Chi-li Province and the heart of China.

But they passed this gateway by, those old Cossack heroes, as the railway builders have passed it by, to press with Poyarkov to the Pacific; to conquer, with Khabarov, the Amur; to meet in desperate conflict the whale-skin cuirassed Koriats of the coast; to battle with the Manchu in conflicts where “by the Grace of God and the Imperial good fortune, and our efforts, many of those dogs were slain”; to fight until but an unvanquished sixty-eight were left of the garrison of eight hundred in beleaguered Albazin.

The current of conquest passed by this door to China, but the swelling stream of commerce searched it out. In 1638, the Boyar Pochabov, crossing Baikal on the ice, broke the first way to Urga, the capital of the Mongolian Great Khan, and gained the friendship of the monarch. In the interests of trade, the deputies of the Czar Alexei Michailovitch followed up the opening with an embassy in 1654 to the Chinese Emperor himself. Over steppe and mountain and desert the mission wound its weary way to Kalgan, the outpost city beside the Chinese Wall, and then on to Peking, bearing to the Bogdo Khan, the Yellow Czar, the presents of Chagan Khan, the White Czar.

From the Forbidden Palace at Peking were started back, four years later, return presents, including ten _puds_ of the first tea that reached Russia. With the presents came a message that drove flame into the bearded cheeks of the Czar and set his Muscovite boyars to grasping their sword-hilts. “In token of our especial good-will we send gifts in return for your tribute.” Thus, the Chinese Emperor.

The answer of the Czar started another legation plodding across a continent, and the retort was thrown at the feet of his Yellow Majesty. It was a summons forthwith to tender his vassalage to Russia. The Czar’s gauntlet had been hurled across Asia. But all it brought was beggary to the traders who had begun to press along the newly-opened route to a commercial conquest of the East.

Soon Russia regretted the fruitage of her challenge. In 1685 Golovin’s embassy left Moscow, and, arriving two years later at Verhneudinsk, opened negotiations with Peking. A Chinese commission then made its way north, and at Nerchinsk, August 27, 1689, was signed the famous treaty closing to Russia her Amur outlet to the Pacific, purchased with such desperate valor at Albazin, but granting to a limited number of Russian merchants trading privileges into China.

A lively traffic at once sprang up. Long caravans, silk- and tea-laden, crossed the Mongolian deserts, the Siberian steppes and hills, and the forested Urals, taking the road to Europe. A little Russian settlement was founded at Peking, and a traders’ caravansary was built. The church constructed by the prisoners of Albazin, who had been so kindly treated by the Manchus that they at first refused the release which the treaty brought, gave place to a larger edifice erected by popes from Russia.

Soon, however, the Russians again offended the Celestial Emperor. In their riotous living, the quickly enriched merchants disquieted the sober Chinese. The Siberians over the frontier gave asylum to a band of seven hundred Mongol free-booters, whom it was urgently desired to present to a Chinese headsman. So commerce was forbidden anew, and most of the reluctant merchants left their compound. Some stayed and assimilated with the Chinese, retaining, however, their religion; and for years a mixed race observed in Peking the rites of Greek Orthodox Christianity.

It may seem strange that rulers so energetic as Peter the Great and some of his successors took no steps to resent by force of arms the arbitrary acts of the Chinese Emperor. But much was going on in Russia; Peter was occupied with his invasion of Persia, and Catherine was without taste for a distant and doubtful campaign. The garrisons scattered over the enormous area of Siberia were numerically too weak and too poorly equipped to do more than hold their own. So, when commerce was once more interdicted and the merchants banished, recourse was had to diplomacy. In 1725 the Bogdo Khan relented enough to receive Count Ragusinsky with a special embassy from Catherine the First, which arranged the second great agreement with China, called the Treaty of Kiahta.

By it the frontier cities of Kiahta in Siberia, and Maimachen, facing it just across the line in Mongolia, were established as the gateway to Chinese trade. The treaty provided for the extradition of bandits and for a perpetual peace and friendship between the high contracting parties. Ever since, the citizens of Kiahta have alternately blessed and blamed Ragusinsky,--blamed him because, in the fear lest any stream flowing out of Chinese into Russian territory should be poisoned, he settled the boundary city beside a Siberian brook so inadequate that Kiahtans have suffered ever since for lack of water, with the river Bura only nine versts away in China; blessed him because of the great prosperity the treaty brought to their doors.

The tea carried by this highway became Russia’s national drink. Great warehouses arose, built caravansary-wise around courts. Endless files of two-wheeled carts rolled northward, bearing each its ten square bales of tea, or its well-packed bolts of silk. The merchants grew wealthy in the rapidly swelling trade.

A great Chinese embassy, headed by the third ranking official of the Peking Foreign Office, made its way to Moscow to keep permanent the relations of the two empires. Similarly, a Russian embassy was established in the rebuilt compound in Peking, where a new church arose, whose archimandrite gained a comfortable revenue by selling ikons and crucifixes to the many Chinese converts he had baptized.

Catherine the Second's edict opened to all Russians the freedom of Chinese trade. Its volume, large before, became now even greater. In 1780 the registered commerce at Kiahta had risen to 2,868,333 roubles, not to mention the large value of the goods taken in unregistered.

Tea, a pound of which, if of best quality, cost two roubles in those days, silks, porcelains, cottons, and tobacco, went north, exchanged for Russian peltries, for cloth, hardware, and, curiously enough, hunting-dogs.

An English merchant, who had penetrated to Kiahta in that year, gives an amusing account of the mutual distrust with which the barter was conducted. The Russian going over the frontier to Maimachen would examine the goods in the Chinese warehouse, seal up what he desired, and leave two men on guard. The Chinese merchant would then come to Kiahta, and do the same with the Russian's wares. When the bargain was struck, both together carried one shipment over the border with guards and brought back the exchange.

In growing prosperity, undisturbed, the Kiahta caravans came and went, while elsewhere history was warm in the making.

Napoleon marched to Moscow, to Leipsic, to Waterloo. The Kiahta caravans came and went. The St. Petersburg Dekabrists rose for Constantine and the Constitution. The Kiahta caravans came and went. The Crimean War saw the Russian flag flutter down at Sevastopol. Even as the Malakoff was stormed, a Russian army marched into Central Asia to seize the Zailust Altai slope, which points as a spear toward Turkestan and India, and a Russian navy sailed under Muraviev to occupy the forbidden Amur. The Kiahta caravans came and went.

At length a railroad, pushed year by year, reached the Pacific. One branch cut across the reluctantly-accorded Manchurian domain to Vladivostok; another struck southward to Dalny and Niu-chwang. The Russian Eagles perched at Port Arthur and nested by the far Pacific.

The camel-commerce of the old overland road across Mongolia shrank now as shrinks a Gobi snow-rivulet under the burning desert sun. The meagre Kiahta caravans became but a gaunt shadow of the mighty past. Only an intermittent wool-export and a dwindling traffic in tea to the border cities remained of the great tribute of the Urga Road. As trade vanished from their once busy warehouses, the Chinese merchants were troubled. Perhaps to prayer and sacrifice the God of Commerce would relent? So a scarlet temple rose on the hill by Maimachen. Prosperity came suddenly once again, a new trade rolled north over the historic way. The Mongol cart-drivers returned from far Ulasati. The camel-trains, that had scattered south to the trails beyond Shama, gathered back as antelopes herd to a new spring in the desert.

The God of the Red Temple, the God of the Caravan, had sent the Japanese. As the Amban's executioner strikes off a victim's hand, so had the Nipponese lopped away the railroad reaching down to Dalny and Niu-chwang--the road that was breaking the camel-trade a thousand versts beyond, on the old route by Maimachen and Kiahta. Against the Russian control of the Pacific the Japanese had hurled all their gathered might. By battle genius and efficiency the Island soldiers won, and athwart the front of Slavic empire they set their desperate legions. Far more was lost to Russia than men and squandered treasure, far more than prestige and power of place. The enormous stakes, even in the port of Dalny, in the forts of Port Arthur, in the East China Railway, were but incidents. The real tragedy of the war was that the vital terminus of her continent railroad was alienated, and that her civilization was barred back indefinitely.

The soldiers and statesmen who carried Russia's power across a savage continent had sought out many inventions. But by whatever means each successive territory was won, its maintenance had been by the warrant that the Slavs had gone not lightly, adventuring to conquest, but as an earnest host clearing a way for the homes and the hearths of their race. The colonist had followed the Cossack; cities and villages, railways and telegraphs, had risen behind the armies. The dawn of the twentieth century saw a mighty expanse of Siberia redeemed from a desolate waste to a land of farms and villages, of mines and industries; a native population, once hardly superior to the American Indian, not, like him, displaced and exterminated, but raised side by side with the settlers to a more equitable place than is held by any other subject people in Asia. The Russian advance had brought the establishment of the volunteer fleet plying from far Odessa to Vladivostok, and the completion of the greatest railway enterprise the

world has ever seen. It had opened from Europe to the Far East a land-route more important to more people than the water-route discovered by Vasco da Gama. The fruition of a nation's hope was lost when the Eagles went down at Port Arthur.

For those who feast at Russia's cost the reckoning is long. Predecessors not unfamed are worthy of remembrance: the Tatars who lorded it four hundred years, the Poles whose kings caroused in the Kremlin, the great Emperor, with his Grande Armée, whose stabled horses scarred the walls of St. Basil, the Turks, the Swedes,--all conquerors of yesterday. But long years must take their toll of life and gold before Russia can carry the entrenched lines along the Yalu, and reënter the redoubts hewn in the sterile hills around Port Arthur. The spoils to the victors for the present are unchallenged. The Russian way to China is not now through Manchuria.

But the ancient road of the Kiahta caravans is still unblocked. Here is the shortest route from Europe to the East. Here, through the defiles and the broken foothills of the Gobi Plateau, lies the future redemption of the great unfettered land-route to North China. The Chinese are themselves advancing to anticipate it. They have already built into Kalgan. To this trading-centre across the pale, a Russian railway may yet pass and her colonists make fruitful the unpeopled wilds of Mongolia.

In the cycles of progress old paths are reworn. Pharaoh's canal from the Mediterranean to the Red Sea was swallowed up under the sands of three thousand years when the Genoans won a way across the Isthmus. Their track was left unsought when the Portuguese showed the route for ships around the Cape. Yet to-day the Strait of Suez is thronged with reborn commerce.

The first American highway to the Western Reserve was superseded by the better avenue of the newly built Erie Canal, yet came to its own again beneath the tracks of the Baltimore and Ohio. So, far to the westward of Japan's outpost, the age-old caravan road, with a shadowy fantastic history dim as its dun trail across the desert, may rise to a resurrected glory as a new road to China.

Its greatness is of yesterday and of to-morrow. Unto to-day belongs the quaintness of the cavalcade that passes to and fro along its track. Over the frozen snows of winter and the rocky trails of summer there plod horse and ox and camel, sleigh and wagon and cart,--a broken line of men and beasts. Russian posts thunder past with galloping horses, three abreast. Bands of Cossacks convoy the guarded camel-trains of heavy mail for China. One meets troops of boyish recruits, singing lustily in chorus on the tramp northward, and Mongol carts and flat-featured Buriats on their little shaggy ponies, sleepy wooden villages, forests, steppes, swamps, frozen river-courses, mountain passes.

Through the kaleidoscope of races and peoples one moves in a world-forgotten life, a procession of the ages.

[Illustration: CHURCH OF ST. BASIL, MOSCOW (Ivan the Terrible blinded its architect that he might never duplicate the masterpiece)]

On the threshold of Siberia the traveler has turned back in manner, in ways of thought, in government, in everything, to the past. Go into one of these cities,--you are in the Germany of 1849, with the embers still hot of the fire lighted by the republican movement of the young men and the industrials. The seeming chance of victory has passed them by. The iron hand is over all. One hears of Siberian Carl Schurzes, fugitives to America and to Switzerland, of the month-lived Chita Republic, of the row of gallows at Verhneudinsk, of the bloody assizes at Krasnoyarsk.

It is as if one lived when citizens gathered in excited groups in the Forum to discuss the news from Philippi; or as if, from the broken masonry of the Tuileries, there stepped out into breathing actuality the five hundred Marseillaises "who know how to die," fronting the red Swiss before the palace of Louis, the King. Here is the reality of friends in hiding, of files of soldiers at each railway-station, of police-examined passports without which one cannot sleep a night in town, of arms forbidden, meetings forbidden, books forbidden,--all things forbidden. Here as there men thought that the new could come only by revolution. Yet one can see, despite all, the germs of improvement and the upward pressures of evolution.

Move further toward the frontier towns, where the relayed horses bring the weekly mail,--you have gone back a hundred and fifty years. You are among our own ancestors of the days of the Stamp Act. Did the General Howe who governs the oblast from his Irkutsk residency overhear the school-boys of Troitzkosavsk as they chant the forbidden _Marseillaise_, he, too, might say that freedom was in the air. These Siberian frontiersmen shoot the deer with their permitted flint-locks as straight as the neighbors of Israel Putnam, and with spear and gun they face the bear that the dusky Buriat hunters have tracked to its lair.

Our Puritans are there, rugged, red-bearded dissenters, "Stare' Obriachi," Old Believers, they are called, who came to Siberia rather than use Bishop Nikon's amended books of prayer. Yankee-like, outspoken, keen at a trade, are these big Siberian sons of

men who dared greatly in their long frozen march. The grants to Lord Baltimores and Padroon Van Rensselaers are in the vast “cabinetski” estates of the grand-ducal circle, engulfing domains great as European kingdoms.

Go into one of the villages of the peasants transplanted in a body by the paternal Government. Here are the patient, enduring recruits for the army, brothers to the toilers over whose fields the Grand Monarch’s wars rolled back and forth. Though steeped in ignorance and overwhelmed by the incubus of communism, they are capable of real and splendid manhood, and will show it when their world has struggled through into the century in which we others live.

Go to a mining-camp in the Chickoya Valley. It is California and the days of ’49. Histories as romantic as those of the Sierras are being lived out in its unsung gorges,--tales of hardships, of grub-stakes, of bonanzas in Last Chance Gulches.

When the bumping tarantass rolls across the Chinese frontier into Mongolia, it enters a kingdom of the Middle Ages flung down into the twentieth century. Feudal princes, lords of armies weaponed with spear and bow, tax and drive to the corvée their nomad serfs. A hierarchy of priests whose divine head lives in a palace at Holy Urga, sways the multitude of superstition-steeped Mongols, and receives the homage of pilgrims wending their way from Siberia, from the Volga, from Tibet, from all Mongolia, to their Canterbury of Lamaism. In prostrate devotion the penitents girdle the Sacred City before whose hovels beggars dispute with dogs their common nourishment, and in whose compounds princes of the race of Genghis Khan, with armies of retainers, live bedless, bathless, lightless, in the felt huts of their race. Squalid magnificence and good-humored kindly hospitality are linked to utter brutality. Sable-furs and silks cover sheepskins worn until they drop from the body. Here and there among the natives a Chinese trading caravansary, alien, walled, peculiar, stands as of old the Hansa-town, with merchant guilds and far-brought caravan goods.

A way of adventure and strangeness, where the years turn back, is this old road of the Golden Horde, leading down past the ancestral homes of the Turks to the Great Wall.

The Cossack sentries at Kiahta look Chinaward. They have become an anomaly, this hard-riding, fierce-fighting soldier class. The plow has metamorphosed into myriad farms the plains along the Don where once their ponies grazed. Mining-cuts score the hills in the Urals where once they hunted. Villages of Slavonic peasants rise along the Amur. The sons of the old warriors grow into peaceful farmer-folk, differing in name alone from their blue-eyed neighbors. Soon they must disappear in all save picturesquely uniformed Hussars of the Guard, and as a memory, chanted by young men and girls in the Siberian summer evenings when Yermak’s song is raised. The task of the Cossack, to lead in the conquest of kindred native races and to weld these through themselves into Russia’s fabric, is nearly done.

Down the ancient road lies a last avenue of advance. Eastward is Manchuria, where artillery and science grappling must decide the day with Japan. Southward is India, where England’s guarded gateway among the hills can be opened only from behind. But into Mongolia Fate may decree that the yellow-capped Cossacks, drafted from Russia’s Mongol Buriats, shall lead once more the nation-absorbing march of the White Czar. For another memorable ride, the Cossacks, who on their shaggy ponies led the long conquering way across the continent, may yet mount and take the road to China.

II

THE GREAT SIBERIAN RAILWAY

How long to Irkutsk? Seven days now, seven years when last I came.” The bearded Russian standing in the doorway of the adjoining compartment in the corridor-car of the Siberian Express gazes thoughtfully at the fir-covered slope, whose dark green stands in sombre contrast to the winter snows. The train is slowly climbing the Ural Range, toward the granite pyramid near Zlatoust, on opposite sides of which are graven “Europe” and “Asia.” Neighbors with easy sociability are conversing along the wide corridors, exchanging stories and cigarettes, asking each other’s age and income in naïve Siberian style.

Regarding the burly occupant of the next stateroom one may discreetly speculate. From sable-lined paletot and massive gold chains you hazard that he voyaged with the traders’ slow caravans in the days before the railway--that he was a merchant.

“A merchant? _Optovi?_ No, I did not come with the caravans.”

From the triangle of red lapel-ribbon, the rank-bestowing decoration, you venture a second guess.

“Perhaps the _gaspadine_ made the great circuit to oversee the local administrations? He was a government inspector--_Revizor?_”

“_Chinovnik niet navierno_,” he answers. Most decidedly he was not an official. The suggestion causes him to smile broadly. “I was with the convicts,” he says.

Beside the line of rails curves the old post-road winding like a ribbon through the highlands.

“It was by that road we marched. Seven years of my life lie along it.”

The train swings through a cleft hewn in the living rock, steep-sided as if the mountain had been gashed with a mighty axe. It rumbles around the base of an overhanging crag while you look clear down over the white valley, with the miles of rolling green forest beyond.

“Was not seven years a long time for the march?” you venture.

“For a traveler, yes; for convict bands not unusual. We went back and forth, now northward a thousand versts as to Archangel, now west as to Moscow, now south as to Rostov. Again and again our troop would split, and part be sent another way. New prisoners would be added, from Warsaw, Finland, Samara. New guards would take charge. Some groups would go to the West Siberian stations, some east to the Pacific and Sakhalin. I, who was written down for ten years at the Petrovski Works beyond Baikal Lake, with a third commuted for good behavior, had finished my term before I got there.”

“Why did they wander so aimlessly?”

“It seems truly as a butterfly’s flight, but you others do not know the way of Russia. Very slowly, very deviously she goes, but surely, none the less, to her goal. We each came at last to our place.”

A match flares up and he lights another cigarette.

“Shall we not go to the ‘wagon restoran’ for a glass of tea?” you ask.

Along the broad aisles you walk, past the staterooms, filled with baggage, littered with bedding, kettles, novels, and fur overcoats. Everything is in direst confusion, and the owners are sandwiched precariously between their belongings. On the little tables which are raised between the seats, they are playing endless games of cards, sipping tea and nonchalantly smoking cigarettes the while. You pass the stove-niches at the car entrances, heaped to the ceiling with cut wood. The fire-tenders as you pass give the military salute. You cross the covered bridges between the cars, where are little mounds of the snow that has sifted in around the crevices; and a belt of cold air tells of the zero temperature outside. At length the double doors of the foremost car appear ahead, and crossing one more arctic zone over the couplings, you can hang your fur cap by the door and salute the ikon that with ever-burning lamp looks down over the parlor-car. Now you can sit on the broad sofa set along the wall, or doze in the corner-rocker under the bookcase, or sit tête-à-tête in armchairs over a miniature table. Ladies here, as well as men, are chatting, reading, and smoking, for this combination parlor, _fumoir_, and dining-room is for all, not a resort to which the masculine element shamefacedly steals for unshared indulgences.

“_Dva stakan chai, pajolst_” (two glasses of tea, please), your friend says to the aproned _chelaviek_, a Tatar from Kazan.

“_Stakan vodka_,” you add; for you are willing to contribute twenty kopecks to the government revenues if this beverage will help out the memoirs of your friend, the convict.

“_Say chass_,” replies the waiter, which means, literally, “this hour,” figuratively, “at once,” actually, whenever he chances to recall that your party wants a glass of tea and another of vodka. When at length the refreshments have come, your companion gets gradually back to the reminiscences.

“Were your comrades many on that march?”

“Twenty-six from my school in Odessa,” he says. He tells of the tumult in the Polytechnic Academy, when he was a boy of sixteen studying engineering; of the barricade which the students threw up; of the soldiers sent against it; of an officer wounded with a stone, and the sentence to the mines. He tells of the journey, day after day, the miserable company trudging under the burning suns of summer and shivering under the biting cold of winter, ill-fed and in rags. He recalls how this friend and that friend sickened and died; how a peasant-woman gave him a dried fish; how one of the criminals tried to escape and was lashed with the _plet_ until he fainted beneath its strokes.

“We were a sad procession. First came the Cossacks on their ponies, with their carbines and sabres. Then the murderers for Sakhalin, and the dangerous criminals in fetters; a few women next; then we, the politicals; last, more soldiers marching behind. Far to the rear came carts and wagons with the wives and families of the prisoners, following their men into exile. Slowly we went, scarcely more than fifteen versts a day, with a rest one day out of three, for the women. In winter we camped in stations along the road.”

From the comfortable leather armchairs they seem infinitely distant and dream-like, these tales from the dark ages of Siberia. The speaker seems to have forgotten his auditor and to be talking to himself, and soon he relapses into silence. He sits holding his glass of lemon-garnished tea, like a resting giant with his shaggy beard and mighty chest. The drag of the brakes is felt through the train. “_Desiet minute stoit_” (ten minutes’ stop), somebody calls out. Suddenly, with an effort, the man across the table rouses from his reverie, and looks about the car, when the broad smile comes back and he says earnestly:--

“You must not think of that as the true Siberia. It was all long ago--thirty-five years. And you see I who became a _kayoshnik_, a gold-seeker, have prospered, and work many mines. I am glad now that they sent me to Siberia. And many others prosper who came with the convicts. The old dark Siberia dies, but our new Siberia of the railroad lives, and grows great.”

He rises resolutely and shakes your hand with a vise-like grip.

“_De svidania!_” (Till we meet again.)

You rise with the rest, draw on your fur cap and gloves, work into the heavy fur-lined overcoat, and clamber down to the platform. A little wooden station-house painted white is opposite the carriage door. It has projecting eaves and quaint many-paned windows. In front of it is a post with a large brazen bell. On the big signboard you can spell out from the Russian letters “Zlatoust.” This is the summit station of the pass that crosses the Urals. Around are standing stolid sheep-skinned figures, bearded peasants just in from their sledges, which are ranked outside the fence. Fur-capped mechanics, carrying wrenches and hammers, move from car to car to tighten bolts and test wheels for the long eastward pull. Uniformed station attendants are here and there, some with files of bills of lading. As you walk down the platform among the crowd, you come upon a soldier, duffle-coated and muffled in his capote, standing stoically with fixed bayonet. Forty paces further there is another, and beyond still another, all the length of the platform, and far up the line. What a symbol of Russian rule are these silent sentries! And what a mute tale is told in the necessity for a guard at every railroad halting-place in the Empire!

You stroll along toward the engine. Huge and box-like are the big steel cars, five of which compose the train. Two second-class wagons painted in mustard yellow are rearmost, then come the first-class, painted black, next the “wagon restoran” and the luggage-van, where the much advertised and little used bath-room and gymnasium are located. The engine is a big machine, but of low power, unable to make much speed; and the high grades and the road-bed, poor in many places, additionally limit progress. It is apparent why the train rarely moves at a rate greater than twenty miles an hour.

At first you do not notice the cold. But now that you have walked for a few minutes along the platform, it seems to gather itself for an attack, as if it had a personality. You draw erect with tense muscles, for the system sets itself instinctively on guard. The light breeze that stirs begins to smart and sting like lashes across the face. The hand drawn for a moment from the fleece-lined glove, stiffens into numbed uselessness. As you march rapidly up and down the platform, an involuntary shiver shakes you from head to foot. A fellow passenger, remarking it, observes:--

“It is not cold to-day, in fact, quite warm. _Ochen jarko._”

You walk together to the big thermometer that hangs by the station-door. It is marked with the Réaumur Scale, and your brain is too torpid for multiplications. But the slightly built official, known as a government engineer by green-bordered uniform and crossed hammers on his cap, is inspecting the mercury also.

“Eight degrees below zero Fahrenheit,” he says. “Quite warm for January. It is often thirty-five degrees below zero here in the Uralsk.”

It gets colder at the suggestion. The three starting-bells ring, and everybody scrambles into the compartments.

The express rolls onward down the Urals. You stroll back to the warm dining-room and idly watch the groups around. Across the way is an elderly mild-looking officer, whose gold epaulettes, zig-zagged with silver furrows, are the insignia of a major-general. He smokes endless cigarettes in company with another officer lesser in degree, a major, decorated with the Russo-Japanese

service-medal, smart of carriage and alert of look. By the window beyond is a young German, gazing meditatively at the hills and the snow through the bottom of a glass of Riga beer. A rather bright-mannered dame, with rings on her fingers and long pendants in her ears, chats vivaciously in French with a phlegmatic-looking personage in a tight-fitting blue coat which buttons up to his throat like a fencer's jacket. A quietly-dressed gentleman, evidently in civil life, is reading one of the library copies of de Maupassant.

Outside, cut and tunnel, hill, slope, and valley, green forest, white drifted snow, and bare craggy rocks, the Urals glide past. The little track-wardens' stations beside the way snap back as if jerked by a sudden hand, and the telegraph-poles catch up in endless monotony the sagging wires.

The Tatar waiter goes from place to place, clearing off the ashes and the glasses, and getting ready for dinner. There is a table-d'hôte repast, the Russian _obeid_, a meal which starts with a fiery vodka gulp any time after noon, and tails off in the falling shadows of the winter sunset with tea and cigarettes. Or, if one wishes, he may press the bell, labeled in the Græco-Slavonic lettering, "Buffet," and dine à la carte.

"Il vaut mieux essayer le repas Russe," says the quiet reader of de Maupassant, joining you.

He is duly thanked for the advice, and we beckon to the aproned waiter. At once the latter passes the countersign kitchenward to set the meal in motion, and puts before us the little liqueur-glasses and the bottle of vodka. While we still gasp and blink over this, he has gotten the cold _zakuska_ of black rye-bread and butter, _sardinka_, salty _beluga_, and cold ham, and has started us on the first course. Then comes in, after the omni-inclusive _zakuska_, a big pot of cabbage-soup which we are to season with a swimming spoonful of thick sour cream. The chunky pieces of half-boiled meat floating in it are left high and dry by the consumption of the liquid. The meat becomes the third course, which we garnish with mustard and taste.

"Voyons!" the Frenchman observes. "Of the Russian cuisine and its method of preparing certain food-substances one may not approve. Frankly it calls for the sauce of a prodigious appetite. But contemplating the _obeid_ as an institution so evolved as to fit into the general scheme of life, it finds merit. The Russian meal is a guide to Russian character."

"What signifies this mélange of raw fish, eggs, and great slices of flesh, and mush of cabbage-soup?"

"Not that the Russian has no taste. It is that he sacrifices his finer susceptibilities to his love of freedom. A regular hour for meals would seem to him a sacrifice of his leisure and convenience to that of the cook. The guiding principle of the national cuisine is that all dishes must be capable of being served at any time that the eater feels disposed."

This is a problem to put to any kitchen, we allow. Napoleon's chef met it by relays of roasting chickens. But one cannot keep half a dozen fowl going for each household of the one hundred and forty million inhabitants of Russia. Thus sturgeon is provided, and sterlet, parboiled so that it tastes like blotting-paper; and the filet that is called "biftek," and the oil-sodden "Hamburger," that is dubbed "filet." These can be started at nine in the morning, and be removed at any time between that hour and nine at night, without any appreciable change in taste or texture. The cook of the restaurant, like his brethren of the Empire, has laid his professional conscience sacrificially upon the national altar of unfettered meals. If the _obeid_ is not a triumph in culinary art, it is at least a signal example of domestic generalship.

We have advanced without a hitch to roast partridge, with sugared cranberries, which our friend washes down with good red wine from the Imperial Crimean estates. We get through a hard German-like apple-tart, and reach the last item of cheese.

When the mighty meal is over, we order tea, light cigarettes, and lean back in the armchairs to chat and note how our neighbors are getting through the time.

At the far end of the room a Russian has joined the French lady and her escort. They are celebrating some occasion that requires heaping bumpers of champagne. The babble of their conversation is in the air. It seems to refer to the comparative appreciation of histrionic talent in Rouen and Vladivostok!

Somebody is being treated to a dressing-down in the latest Parisian argot. "Ces sont des betteraves là-bas!" one hears scornfully above the murmurs.

Across the way some Germans are engaged with beer-schooners. One of them gets excited and brings his fist down upon the table. "Arbeit in Sibirien nimmer geendet ist; they always want more advice about their gas-plants."

In the lull that follows the explosion, a gentle English voice floats past from the seat behind us. “And so I told him that the station had nearly enough funds, but we needed workers, more workers.” It is the English medical missionary on his way to Shanta-fu, discussing China with the American mining-engineer, bound for Nerchinsk.

The piano, under the corner ikon with its ever-burning lamp, tinkles out suddenly, and a man’s voice starts up--

You can hear the girls declare, He must be a millionaire.

He misses a note every now and then, which does not embarrass him in the least. Caroling gayly to his own accompaniment, he forges ahead. The crowd in the armchairs around the room, consuming weak tea or strong beer, and smoking, all join with an untroubled accord and versatile accents, French, English, and Russian, in the blaring chorus, “The man that broke the bank at Monte Carlo.”

The train rocks faster on the falling grade; little by little the mountains drop away; gradually the mighty forests become dwarfed into scattered clumps of straggly birches, and the great trees dwindle into bushes; lower and still lower fall the hills, until all is flat. As far as the eye can see are the snow-covered wastes, treeless, houseless, lifeless. The lowest foothills of the Urals have been passed. It is the beginning of the great steppes.

Slowly the daylight wanes. The gray darkness deepens steadily; it seems to gather in over the gliding snow, and the peculiar gloom of a Siberian winter’s night closes down. At each track-guard’s post flash with vivid suddenness the little twinkling lanterns of the wardens of the road. Involuntarily conversation becomes less animated and voices are lowered; the spell of the sombreness is over all.

Soon the electric lamps are lighted, and from brazen ikon and sparkling glasses flash reflections of their glitter. Curtains are drawn, which shut out the enshrouding blackness. The piano begins tinkling again; the waiters come and go with tea and liqueurs; the babble of conversation rises; and the idle laughter is heard anew. Darkness may be ahead, behind, and beside, but within there is light--enjoy it.

The train slows for a halt. Station-lamps shine mistily through the brooding night. Lanterns bob to and fro on the platform as fur-capped train-hands pass, tapping wheels and opening journal-boxes. At each door a fire-tender is catching and stowing away the wood which a peasant in padded sheepskins is tossing up from his hand-sled below. It is Chelliabinsk, whose old importance as the clearing-house of the convicts has been passed on to the new city of the railroad. Here the just completed northern branch, linking Perm to Petersburg, meets the old southern line from Samara and Moscow.

A short stop and the train moves on again. The day is done and gradually each saunters into his own warm compartment, which the width of the Russian gauge makes as large as a real room. One can read at the table by the window, under the electric drop-light, or, propped in pillows, one can stretch out luxuriously on the easy couch that is nightly manoeuvred into an upper and lower berth. Practically always after crossing the Urals, the number of passengers has so thinned out that each may have a stateroom to himself.

Presently you push the bell labeled, “Konduktor.” A uniformed attendant appears standing at the salute. “_Spate_” (sleep) is sufficient direction. The sheets and pillows are dug out and the transformation of the couch into a bed is effected. “_Spacoine notche_” (good-night) he says, and you fall asleep to the rhythmic throb of the engine.

During the following hours the train enters the Tobolsk Government, the oldest province of Siberia, whose 439,859 square miles of area, nearly four times as large as Prussia, extend roughly from the railroad northward to the Arctic Ocean, and from the Urals eastward so as to include the lower basin of the Ob-Irtish river system. This ancient province has seen much of Siberia’s history, whose predominant features have been two, growth and graft.

[Illustration: BRIDGE OVER THE IRTISH]

[Illustration: ALONG THE TRANS-SIBERIAN RAILWAY]

Out of evil, somehow, in a marvelous way has been coming good. In the earliest days, with what smug satisfaction did the Stroganovs find that the native inhabitants would trade ermine for glass beads! Yet the fruit of their sharp dealing and purchased protection and special privilege was the expedition that won Sibir, founded Tobolsk, and opened to Russia the way into northern Asia. The imperial commissioner who came to Tobolsk shortly after Kutchum Khan’s overthrow, to collect the yassak tribute of ten

sable-skins for each married man and five for each bachelor, was detected culling the choice skins for himself, and substituting cheap ones for his master. But his agents had sought out the paths and extended the Russian Empire far into the northern forests.

By despotic oppression the inhabitants of Uglitch town, condemned for testifying to the murder of Dimitri, the Czarevitch, came here into exile in 1593, carrying with them the tocsin-bell that had tolled alarm when the Czar wished silence. But they, together with the deported laborers settled by the same arbitrary will along the Tobol River, started the permanent settlement of the new realm.

A succeeding functionary called on the natives for a special tribute of ermine for the Czarina's mantle. He collected so many bales of it that the taxed began to wonder at the stature of the "Little Mother," and sent a special deputy to Petersburg. The legate discovered that the Empress was as other women, and on his disclosures the official was unable to save his own, let alone the ermines' skins. Yet while the governor was plundering the fur-merchants of Tobolsk, the frontiers were extending, until by 1700 they reached eastward to Kamchatka and Lake Baikal, southeast to the Altai foothills at Kuznetz, and north to the Arctic Ocean.

At Tobolsk in 1710 Peter the Great established the capital of his reorganized province of Siberia. Prince Gagarin, whom he appointed its first governor, found here a systemless extortion unworthy of an efficient statesman. With the thoroughness of genius he built up in the unhappy province a regular organization of rascality. His pickets patrolled the roads into Russia, to prevent the escape of those who might carry the tale of his oppression. He arranged with high officials at Court that any petitioners who evaded this frontier net should be handed over to an appropriate committee. Thus fortified, he began collections of as much as could be wrung from his luckless subjects. Every traveler paid Gagarin's tariff, every farmer sent him presents of stock, every trapper forwarded the best of his catch. The fur-trader's donations and the merchants' loans were assisted into Gagarin's warehouses by thumbscrew and thonged knout.

While these things passed in Tobolsk there came periodically to Petersburg delegations of outwardly contented citizens attesting the wisdom of their governor. They brought to the Czar and the Grand Dukes, in addition to the punctiliously rendered tax yassak, gifts of especially fine furs. Such was the completeness of Gagarin's control that not an echo of the true state of affairs reached the ears of the astute Peter.

At length, in 1719, Nesterov, the Minister of Finance, was privately approached by some Tobolsk merchants and was supplied with evidence sufficient to hang half the officials in Siberia. In a dramatic presentation the Minister furnished this to the Imperial Senate, showing so bad a case that Gagarin's own agents in the ducal circle rose up against him. The Czar sent Licharev, a major of the Guard, to Siberia, to proclaim in every town and hamlet that Gagarin was a criminal in the eyes of the Emperor. As this messenger approached Tobolsk, official after official came out to turn state's evidence, trying to assure his personal safety. The highways to Russia were guarded by Peter's own troops, with orders to seize all outgoing travelers who might be transporting Gagarin's accumulated spoil, which with commendable prudence the Czar had allocated to himself.

When Peter was in England he had remarked casually to an acquaintance, "In my realm I have only two lawyers, and one of these I intend to hang as soon as I get back." It was particularly unfortunate for this ex-governor that the remainder of the legal profession did not feel himself called upon to explain to Peter the Gagarin campaign contributions. No one ever needed an attorney more. He was under trial before an imperial judge who did not know a technicality from a tort, and whose preliminary procedure was to order a reliable gallows.

For some score of years subsequent to Gagarin, the governors of Siberia were, in any event, moderate. The province grew apace, increased by exiles, by land-seeking colonists, by raskalniks,--nonconformists of the Greek Church, self-called "Old Believers,"--who preferred to come to Siberia rather than follow Peter's orders and shave off their beards.

Then Chicherin the Magnificent came. His life was a round of celebrations. Wonderful stews he concocted for his sybaritic revels. At _obeid_ an orchestra of thirty pieces supplied the music. Artillery in front of the residency saluted him with salvos when he drove out. In Butter-Week all Tobolsk drank the spirits which their governor bountifully provided. It is hardly necessary to say that the money for these entertainments did not come from Chicherin's private purse: the city merchants groaned over forced loans and benevolences; and at last their cry reached the throne, and Chicherin too was removed.

With his passing, the Tobolsk Province fell to less spectacular rulers, but under good and bad it grew steadily, until in 1860 there were a million inhabitants within its borders, a population which at the present time has risen to a million and a half. Some forty thousand of these are exiles; some eighty thousand raskalniks; and forty thousand Tatars, who feed the flocks where their ancestors once bore sway, living peacefully side by side with the Russians. Some fifteen thousand are descendants of the

Samoieds and Voguls with whom the first Stroganov from the adjoining Russian province of Archangel traded his wares. Some twenty thousand are Ostiaks whose forebears were alternately allies and enemies of Yermak.

The capital city, Tobolsk, on the Tobol River hard-by its junction with the Irtish, has grown from a precariously held camp of two hundred and fifty fugitive Cossack soldiers to a city of thirty thousand. Tiumen, the easterly city on the Tura River, another of Yermak's camps, has grown into a great distributing-centre for produce brought by the river-highways. From the railway line northward as far as the city of Tobolsk extends a farm-belt, a continuation of the black-earth region of great Russia. The fertility of the land may be judged by the number of villages met as the train speeds on, and the large proportion of enclosed fields on both sides of the track. Some of the finest agricultural soil in the world lies here, such soil as composes the prairies of Minnesota and Dakota. Three million head of live stock graze in the district, which has a yearly production of ten million hundredweight of wheat alone, four million of rye, and nine million of oats. Five million more settlers may live and thrive, and the harvest will feed the ever-growing cities of Europe when Siberia comes to be the new granary of the old world. The stress and turmoil of Tobolsk are passed. Happy the people who have no annals!

Gradually, as the train rolls eastward beyond the Ishim River Valley, the farm country opens out into the unfenced prairie of the Great Steppe. The clustered wooden villages that flanked the line through Tobolsk appear less and less frequently, till at last we seem to glide over an immense white sea, frozen into perpetual calm and silence. Here and there a gray thicket of stunted trees and bushes, here and there a grove of naked-limbed birches, mutely exhibit Nature's desolation.

As the sullen landscape bares itself, one thinks of the prison caravans tramping these wastes; of the early neglected garrisons which Elizabeth's favorite General Kinderman proposed to victual on crushed birch-bark and relieve the Crown of their expense; of all the misery and the wrong that the steppes of Siberia have symbolized. No sign of man's handiwork or of Nature's kindliness is seen,--only the cold snow and the bare birches, while regularly as the ticking of a clock the telegraph-poles and the verst-spaced stations snap back into the wastes. The dominant reflection is not, how great is the achievement which has mastered these steppes! but, how infinitesimal is all that man has done in this ocean of untrodden snow! Hour after hour we are driving on. Yet never is there passed a landmark to conjure into imagination a picture of progress. One moves as in a nightmare, where he runs for seeming ages, hunted forward, yet can never stir from the spot. The horizon-bounded circle of vision is as the ever-receding rim of a giant dome, the rails ahead and behind bisecting its white immensity. Above, the vast bowl of the blue sky dips and meets it, imprisoning us. Where are the fields and villages; the bustling activity of human life that tells of man's mastership? Hour after hour passes without a change in the drear monotony of the landscape; for miles on miles not a trace is seen of human dominion. Grim Nature spreading her shroud over plain and pasture is despot here, and Winter is ruler of the Siberian Steppe.

One could ride due south a thousand versts, through Golodnia the "hunger steppe" to the borders of Turkestan, and find the same monotonous plain, snow-covered save where the dryness of the south has thinned its fall. One could ride from the Caspian Sea due east to China, with each day's march a counterpart of the rest. Five hundred thousand square miles of area are covered with grass and gaudy flowers in the spring, with low brush and green reeds where the salt swamp-lakes receive the tribute of snow-fed streams. In midsummer the growing grass scorches under a heat of 104°. In winter snow is everywhere,--in feathery flakes that the midday sun does not soften during whole months of a cold which is a ferocity. Thirty to forty degrees below zero is not unusual, and the land is swept by bitter winds that pierce like daggers through doubled furs and felts. Yet there dwell on the central plateau of Asia a million people, and one million cattle and three million sheep are scattered over the tremendous range. As the herds have become hardened through the centuries and survive in measure despite the severity, so also have the men. From the train-windows now one may chance to see infrequent straggling herds of long-horned cattle, lean and gaunt, scratching away the snow in search of food. Mounted on little shaggy ponies are figures buried in skins, who keep guard over them.

One detects a new type among the crowds at the stations,--flat faces, round eyes, square thickset bodies. Here on the borderland, the old race has fused with the Slav and has become metamorphosed. The sons of the Tatars, whose very name was distorted into that of a dweller in Tartarus by those who feared their fierce valor, have become shopkeepers, train-hands, waiters, and butchers, who come to sell meat and milk to the chef of the wagon restoran. Sometimes, at the stops, figures, gnome-like in enveloping red capote and grotesquely padded furs, hold their ponies with jealous rein, staring curiously at the locomotive and passengers.

[Illustration: DINING-CAR SALOON, VIEW OF THE LIBRARY]

Looking long from the windows at this steppe, a drowsy hypnotism steals over the mind--a dull stupor of unbroken monotony. It is better to do as the Russians--pay no attention whatever to the landscape outside, but make the most of the life within the moving

caravansary,--cards and cigarettes and liqueurs, tea and endless talk, with yarns that take days for the spinning.

The uniformed judge, passing by, joins you. He is traveling to a new appointment with his swarming family of children, shawl-decked females of unknown quality and quantity, the household bedding, and the ancestral samovar, all crowded into one stifling compartment. He discusses volubly the confusions of the Code, and propounds a unique theory of his own as to Russian jurisprudence, to the effect that all the best laws of other nations have been adopted, with none of the old or conflicting enactments repealed. The general drops into the circle. He is interesting when one has pierced the crust, but dogmatic. At every station the soldiers of the garrison, not on sentry-duty, jump to one side, swing half-around, and stand at the salute until he passes, to the huge inconvenience of the porters. He would undoubtedly vote the Democratic ticket to repay Mr. Roosevelt for putting Russia under the alternative of stopping the war perforce, or forfeiting sympathy, when Japan was said to be breaking under the strain.

“Russia was beaten this time. What of it? _Nietchevo!_” says the general.

“_Nietchevo_,” we echo, as we sip our tea.

“But the Japanese are wily insects,” observes his companion, the young service-medaled major. “I was in Vladivostok when our prisoners came back. They tried to get money for the checks the Japanese had given them. That was how the big mutiny began. You know, when our men were taken captive, the Japanese treated them very well, much good food, vodka, let them write home all about it, and gave them enormous pay, six yen, three dollars a month, charging the expense all up to the Czar for after the war. When at last the prisoners were to be released, the Japanese promised every man double pay, twelve roubles. But they gave them the money? No, the insects gave them each an order payable by the Russian commander in Vladivostok. So the transports came, and these men were sent ashore with these checks in their hands, and they went up to the commandant of the city, and asked for their cash that the Japanese had promised. What money did the commandant have for them? What could he do? He ordered them to go away. So they stood and discussed on the street-corners. And more men still came from the transports. Then they said, ‘We will ask the general of the forts.’ So they marched to the forts in a big crowd, and the general he also told them to go away. For a long time they talked and they persuaded the sailors to help them. So they went again to the forts, and the sailors shot at the forts, and the general ordered the artillery to shoot. But the artillery would not, so the men broke in and killed the officers and got arms and went back to the city commander. Him, too, they killed, and all Vladivostok was in mutiny for two weeks. Not an officer dared show himself. General Orlov persuaded them to let him into the town. Then many were shot, but at last the city was quiet. The Japanese are very sly insects.”

His story ends and the two officers go back to join their families. The train throbs on across the steppe.

The German gas-plant drummer, with his new Far Eastern outfit, is gathering from the missionary doctor details of treaty-port life, which are being treasured up as valuable reference data. The French fur-merchant dips back into his library copy of de Maupassant.

The rigor of the outside scene seems at length to be changing. A few scattered houses appear, and trees and fenced fields, and villages, with curling smoke rising from the chimneys. Men and children are walking about, and finally we come to the Irtish River, over which the train rumbles on a half-mile bridge. Spires and gilt domes are visible, dark wooden houses, and bright white-painted churches with green roofs. Droshkies and carts are passing in the streets, and presently we draw up to the station of Omsk, the second city of Siberia.

The junction of the Trans-Siberian Railway with the Irtish River, which is 2520 miles long and open from April to October, would of itself make Omsk a centre of great strategic importance. But in addition to this main river-highway, which is navigated by some hundred and fifty steamers, there are affluents by which one can sail from the Urals to the Altai, from the Arctic Ocean to China, and these lines of communication centre here.

From Omsk, following the Irtish down past Tobolsk, one can steam by the Obi to Obdorsk, within the Arctic Circle. Indeed, a regular grain-export service was planned via the Kara Sea to London by an ambitious Englishman. It failed after some promise of success, because of the ice-packs in the Gulf of Obi. From Omsk, following the Irtish upstream, steamer navigation extends as far as Semipalatinsk, in the Altai foothills. Smaller craft may go nearly to the Chinese frontier.

By the Tobol and Tura rivers, Tiumen, in the Ural foothills, may be reached, four hundred and twenty miles from Semipalatinsk. By ascending the Obi, a boat may go fourteen hundred and eighty miles east from Tiumen to Kuznetz on the Tom; through a canal from an Obi confluent the Yenesei River System may be entered, and from it by a short portage the Lena System. In all

twenty-eight thousand miles are navigable by small craft, and seven thousand miles by steamer. Omsk is the pulsing heart of this mighty interior waterway system.

[Illustration: TIUMEN TOMSK PERM CITIES OF NEW RUSSIA]

The train leaves the station, which is at a distance from the town, and once more we are en route. The eye rests gratefully upon the ribbon of cultivated fields which follow the Irtish down. But we reënter the steppe, and again the desolation settles over all. In hours of looking, not a habitation is seen, not an animal, not a tree,--only the same white billows. This Barbara district in the Tomsk Government has an area of fifty thousand square miles. Kainsk, some seven hundred versts from Chelliabinsk, is the centre. The section, though covered with the fertile black earth of the adjoining regions, is, owing to lack of drainage and adequate rainfall, arid and almost untilled.

The round-faced civilian from the compartment further up, whose familiarity with the country has made him a welcome accession, joins us at the window. He looks out over the level plain of the Barbara Steppe with manifest satisfaction.

“You admire the landscape?” we ask satirically.

He smiles. “We got big money when the line went through here. I made my first fortune then.”

He sighs at the memory of old times, and tells of the railway-building days when the Czar had given the order for a road across the continent, and the soldiers of fortune, of whom he was one, had gathered to the task.

“Not a kopeck had I when the Dreyfus brothers made their big speculation in Argentine wheat and went down, leaving us young clerks stranded in Kiev. You know Kiev? Great pilgrimages come there to see the bodies of Joseph and his brethren, all preserved just as when they died. We heard by accident of a grading job under a big contractor out here. None of us knew anything about construction, but three of us grain-clerks wrote a letter saying we would put the work through, and started. We had just enough money to get to Samara. In Samara was a merchant much esteemed, whom I went to see. He went on our bond, never having seen us before, and gave us enough money to come. So it was in the old days. The country was flat as a board. We had but to lay down the ties and spike the rails. Thirty versts we made of this line. It cost us thirty thousand roubles a verst, but we got fifty thousand. Would that we might do that now again.”

The contractor, his round jolly face glowing with the recital and his eyes shining through gold-rimmed glasses, is entertaining a growing company, for the judge has stopped to gossip, and the railroad official.

“I took my money and bought an estate in the country of the Don Cossacks,” the contractor is saying. “I paid ten per cent to the Government for taxes when I bought the land. I had to pay no more taxes then all my life, but my heir would pay taxes, or, if I sold, he who bought would pay. So it was done in the Hataman Government.”

“It is just,” says the judge. “Why should they, who get the property, not pay taxes?”

The contractor shrugs his shoulder and continues: “For five years I farmed, and though I had a German overseer, I did not prosper. So I went to one of the cities of Russia and thought to put in a tramway. The men of the city said, ‘Are all the horses dead? He of the spectacles is mad.’ Yet by importunity I got them to give me the right to make a tramway. There were in Petersburg then many Belgians, with much money, wishing to give it away. So I went to them and said, ‘Here is a great franchise, but who will build the line and gain the riches?’

“‘We will, we will,’ said the Belgians.

“From them I got a hundred and eighty thousand roubles clear, and an interest. I sold the interest quickly to other foreigners, Frenchmen, and went away. Yes, the tramway was built, and the people crowded to ride on it as I had said. But when it was going well, and the profits were yet to come, the people said, ‘Shall foreigners oppress our city?’ So the town bought the tramways for what they said was the cost, and the Belgians went away. And they did not come back to Russia. Thus were many railways and tramways built and taken. The foreigners will not come back now, and Russians too do not enter these pursuits, lest the Government come after them later. It is _hudoo_ (bad).”

“But is it not worse that these men should make a tramway and draw vast money from the people?” says the railroad official. “For me, I think the Government should do it all.”

“_Ni snaia_, I don’t know,” says the contractor. “But I who bought stocks with the Belgians’ money (foolishly thinking that the business which I knew not was safe, while that which I knew was shaky), I will not give again to the stock-people the money I shall make from the oil-fields of Sakhalin, where I go now.”

“But,” says the railway chinovnik, “does not the State do these things better? Look you at this very railway. For years any who wished might have built into Siberia. An Amerikanski, and Collins, an Angleski, came proposing railroads, but all things slumbered. Then in 1891 the Czar ordered the road to be built, and in ten years we had laid the eight thousand versts to Vladivostok. I read that the line of Canada, where too there are steppes and highlands as ours, took ten years for but half the distance. We made two versts a day for all the years, and they but one. Who other than the Government could spend a billion roubles for a line that will bring money returns only in the far future?”

“Ah, you chinovniks, you say, lo, we do all this! But it was such as I built that road, and because you gave us big money. And is not the money to support it now got from the peasants’ taxes while so many clerks and operators waste time in the offices? I have seen a third as many men as at Omsk do the same work. And your trains go as the water-snails, twelve versts an hour for freight, twenty versts an hour for the mail-trains, thirty-five versts for the express. One can go eighty versts in Europe.”

“Truly, truly, but why go so fast? It costs more for fuel, and the track has to be made straight. What good does it do you to come in sooner? If a man is in a hurry to get somewhere, can he not take an earlier train?”

The group mulls over this knotty point of logic, which is complicated by the fact that our own train is twelve hours late. They cite hypothetical men with varying sorts of engagements, and then lightly switch to talk of the nourishing properties of beer, the utility of agricultural machinery, and the old tiger battue of Vladivostok.

The birch groves become more frequent now, pines begin to appear, and at last the country has become forested. Several of the passengers bestir themselves for departure, gathering multitudinous bundles, and making the circuit in demonstrative hand-shaking farewells.

“We come to Taiga, whence they go to the stingy town of Tomsk,” the government engineer observes.

“Why do you call it the stingy town of Tomsk?”

“I will tell you. Tomsk, before the railroad came, was the biggest, finest, and wealthiest of our cities. She was the capital of the great Tomsk Gobernia, with three hundred and thirty thousand square miles of area, and a million and a half people. The Tom brought the big river steamers to her wharves. In the city she had sixty thousand inhabitants, increasing every year; a university, Stroganov’s Library, a cathedral, fine public buildings. The merchants were rich; the miners came down from the Altai; all things were prospering. When the railway was ordered, the engineers came through to locate the line. All they asked was a hundred thousand roubles. But how stingy were the people of Tomsk! They had given two million roubles for their university, where the students made speeches and got sent to the Yakutski Oblast, yet they would not give a hundred thousand roubles to the engineers. ‘Give fifty, give even forty thousand,’ said the engineers. But the people of Tomsk said, ‘Are we not the seat of government for all western Siberia? Have we not Yermak’s banner in the cathedral? Are we not Tomsk? You must bring the railway here anyway.’ But if the engineers had done that, who could say where it would have ended? All the other cities would begin to make excuses. So the grades to Tomsk became suddenly so bad that the line had to be run away south here, eighty-two versts. The station where one changes was named, in mockery, Taiga, ‘in the woods.’ The merchants flocked out begging the engineers to come back to Tomsk. They offered all that had been asked and much more. They hung around the office and wept over the blue-prints. But how can a professional man change his plans and sacrifice his reputation? One cannot do such things. So Tomsk was left, and her trade now falls far behind that of the other cities, Omsk and Irkutsk. We in Siberia smile at her and call her the stingy city of Tomsk.”

“We have, too, another jest, of the Tomsk Czar,” chimes in the judge. “There appeared one day there a stranger calling himself Theodore Kuzmilch, who bought a little house which he never left save to do some act of charity. For years he lived; then, when he died, the house was turned into a chapel because of his good deeds. Many years after his death, a merchant started the tale that this was the Czar Alexander I, who did not die in the Crimea, but left a false body to be carried to Petersburg and entombed in state. He had, it was told, not really died, and, disappointed at his powerlessness to help his people, had come, self-exiled, to Siberia. But we others laugh at this tale of Tomsk as an imperial residence.”

The twenty minutes’ stop at Taiga ends, and the train renews its journey through the forests.

With rolling hill and long-stretching forests, the watershed bounding the eastern limits of the Obi Basin is crossed near Achinsk, and the drainage-basin of the mighty Yenesei River, one million three hundred and eighty thousand square miles in area, is entered. It just fails to equal in length the Mississippi-Missouri System. Including the administrative territory “Yeneseik” of the East Siberian Gobernia, the river sweeps from the Chinese borderland north beyond the Arctic Circle. In the far south, where it rises among the Minusink Mountains, the valley country is like the Italian Alps, mild and very fertile. Iron-mines of prehistoric antiquity are found in these valleys, relics of the old Han Dynasty of China.

Of the twenty million bushels of grain produced throughout the Yeneseik territory, nearly a third comes from the Minusink oasis. The railroad pierces the central plains, farmed in the most favorable spots only, and capable of enormously extended cultivation.

Through alternating forest, field, and plain the train moves on, and crossing the three thousand-foot Yenesei bridge, enters the city of Krasnoyarsk. When we pull out, the engineer, who has been chatting with the erstwhile contractor, observes, “This town was a main hotbed of the great strike. They are well in hand now, but we had our time with them in 1905. Even I knew nothing of what had been prepared.”

He goes on to tell the most curious tale of the organized strike movement which introduced the disturbances subsequent to the Russo-Japanese War.

“On September 15 at noon, no one knows by whom or from what station, a signal of dots and dashes was tapped off. Each telegraph-operator answered the message and passed the word to the next, standing by until it was repeated back. Then, leaving all things in order, he stepped from the operating-room into the railway-station. With a motion he gave the countersign to the ticket-sellers, and each, as he received it, shut his desk, and walked out. The word went to the engineers, and each, at the signal, drew his fires and left the engine and its train forsaken on its tracks. Every postman put away his mail, closed the safe, and left his office; every diligence-agent locked his doors. From Astrakan to Archangel, from Warsaw to Vladivostok, the electric summons went, and the whole realm of Russia was paralyzed.

“With two thousand roubles, offered by the Governor-General of Poland, before them, and ten bayonets on the tender behind, an engineer and a fireman were secured to run one coach, containing a terrified prince, from Warsaw to the frontier. In the south, a few cars were started by soldiers, but beyond such rare instances, for three weeks not a train was moved. More than this, not a telegram was transmitted, not a letter delivered. Everywhere was black silence, as if all the Russias had been swept from the face of the world.

“‘More wages, and the constitution,’ was the slogan of the strikers. The official cohorts met the issue courageously, with bribes and bayonets, and little by little got the upper hand. Force and money were used unstintingly to win the operators needed and break the front of the strike. A few, who, contrary to the expectations of their mates, had remained loyal to the officials, were finally secured and protected by the soldiery. As in time one train after another was manned and moved, the men who had stayed away lost heart, knowing but too well what would be the fate of those who were left outside the breastworks. First singly, then in crowds, they returned, and the great strike was broken.”

“Here in Krasnoyarsk there was revolutionist rule for a while as well,” the manager remarks. “The troops were driven out, and we had to wait for reinforcements. Yet when I came to my office there were sixty thousand roubles in the safe, not a kopeck of which had been touched. Some of the best employees were condemned. I was very sad, and the service was very poor when they marched away.”

“What became of them?” we ask.

In a low voice he answers, “They went to the Yakutsk.”

Everybody is silent for a moment.

“Where did you say?” inquires the missionary.

“The Yakutski Oblast,” answered the chinovnik.

In Europe people talk of the rigors of Russia’s winter. In Russia of the cold of Siberia. In Siberia, along the railway, when the thermometer gets down into the forties and the sentries pick up sparrows too numb to fly, they say, “It’s as cold as the Yakutsk.”

“One starts to the Yakutsk by the steamer-towed prison barge, following down the Yenesei from Krasnoyarsk,” the engineer continues. “For the first thousand versts northward the way is through a mighty forest region. The interior is almost as unknown as when the Samoieds were its sole inhabitants. Marshes covered with trembling soil, to be crossed only on snowshoes, alternate with thickets, called _urmans_, of larches, cedars, firs, pines, and beeches.”

“It is not alluring,” we observe.

“The cold of the winter seems largely to arrest decay, and the fallen trees, remaining unrotted, form a nature-made _cheval de frise_, impossible to traverse save along the hunters’ trails. Another thousand versts up the Upper Tunguska River, at whose limit of navigation is a crossing into the Lena System, and the Yakutsk Province begins; eastward to the coastal range overlooking Behring Sea, and northward to the Arctic Ocean, a million and a half square miles of desolation, extends this exiles’ oblast. Prison-stations are located in the forsaken tundra country beyond the Arctic Circle, where scattered clumps of creeping birches and dwarf willows struggle to maintain existence in the few unfrozen upper inches of ground, congealed perpetually beneath to unmeasured depths. Here, where the average winter temperature is eighty below zero, come the exiles deemed most formidable.”

“How long do men last in the Yakutski cold?” we ask the engineer.

“Oh, sometimes a strong man will outlive his sentence and return. The friends of our strikers ask me sometimes about one or another, but we have heard nothing of them since they marched away in chains. May fate keep us from that road!”

The theme is not enlivening, and soon we go forward into the observation-car.

After crossing the Kan River at Kansk, the railroad turns abruptly southwest, through the hilly country of the Irkutsk Gobernia, and climbing into the highlands of the Altai, enters the watershed of the Angara. The drainage-basin of this river equals the combined areas of Iowa, Illinois, Indiana, Ohio, Pennsylvania, and New York. It is as well adapted to agriculture as parts of the best provinces of Central Russia in the same latitude.

The train pulls next into the station of Nishneudinsk. A booted peddler is making his way down the platform, with knives, combs, caps, and cheap knick-knacks. He stops to show us something special, a miniature of multicolored minerals, glittering from a hundred crystal facets. The Russian engineer picks out the flaky quartz, the iron pyrites,--“fools’ gold,” as they called it in old Nevada times,--green porphyry, iridescent peacock ore of copper, and some black crystals like antimony, which show here and there. Malachite, serpentine, topaz, and numberless other minerals are in the mass, which glitters in kaleidoscopic changes. A small piece of gold ore tops the pile.

“Cabinetski?” asks the engineer.

“Da, da,” assents the peddler. “Cabinetski.”

“It comes from one of the domains of his Imperial Majesty’s Cabinet,” explains the engineer. “Stretches of forest, belts of fertile river valley, fur districts, hundreds of thousands of square versts, the best mines in these Urals which produce sometimes yearly seven million roubles, the entire Nerchinsk region, producing six million roubles, are ‘cabinetski,’” he remarks. “Even I, Ivan Vasilovich Poyarkov, am ‘cabinetski’!”

He explains the origin of the term, going back to the old days when princedoms went to the courtiers of Catherine. Always for a great enterprise it was necessary to have a friend at Court. So the rich merchants and miners would form, with powerful members of the inner circle at St. Petersburg, alliances such as that made by the Stroganovs with Boris. Gradually, as time went on, the protected were swallowed by the protectors, until one by one the various estates had passed into the hands of the nobles of the Imperial Court. The mines in the Altai, which Demidov had opened up, were taken over in 1747 by the Emperor, those in the Zabaikalskaia Oblast at about the same time. With the passing of the years, what had been graft and expropriation was transmuted into vested interest, until now it is the established right of the Imperial Cabinet, or the Grand Dukes, to receive the revenues of these vast domains. In the mining regions their perquisite is from five to fifteen per cent. Save for the tax, however, miners are free to operate upon the ducal estates, and many are thus engaged.

A fur-capped station-agent clangs the big bronze bell, waits a moment, and then clangs twice. The passengers climb back into the box-like steel cars of the express. The third bell sounds, and the train starts. We sit down beside the engineer and the conversation takes up the “cabinetski” again.

“We have great traditions. One Governor, Neryschkin, of the ‘cabinetski’ mines at Nerchinsk, marched to fight the Czar. In 1775 he was appointed chief of the mineral belt in the Zabaikalskaia Oblast. He sat for eleven months at home with closed shutters. Then, on Easter Sunday, singing a devil’s hymn, and with a fat female on either side, he drove to church and ordered the service amended to suit a rather bizarre taste. He organized a series of glittering shows at the Crown’s cost, gave free drink to the populace, and throwing out many of his subordinates, appointed convicts in their stead. When he had used up all the tax-money in his keeping, he drew up cannon before the house of the rich merchant Sibirayakov, the operator of the mines, and made him hand out five thousand roubles. Finally he got together an army of Tunguses and the peasants, to march against the Czar. He was caught on the way and sent to Russia for punishment. It is the great honor of our service to be governor over the ‘cabinetski’ mines. Perhaps I shall rise there some day. Perhaps not. But I shall not march against the Czar.”

The forests of birch and pine and fir, and the hills, as the car drives eastward, close in again. The crests of mid-Siberian mountains lift their snowy heads, and the train climbs up and up toward the great central Lake Baikal, and the city of Irkutsk, 3378 miles from Moscow, and further east than Mandalay.

When, on this seventh day, the train is winding up the Angara Valley toward Irkutsk, one may mentally look back over the country that has been traversed and estimate somewhat the meaning of the railway. The Urals formed the first landmark. As in the dominion of the blind the one-eyed man is king, so after the monotony of the plains, the Ural Mountains seem great and worthy of the name given by the old Muscovite geographer, the “Girdle of the World.” By actual measurements, however, in their seventeen hundred miles of length, no peak rises over six thousand feet. Coming eastward from the Urals the line has cut through the southwestern corner of the old Tobolsk Government, has skirted the northern border of the steppe, has bisected the Tomsk Province, and after crossing the Yenesei River in Yeneseik has entered Irkutsk Province, and traversed the central highland region nearly to Lake Baikal.

Many who journey this way will have as their first impression, when the long winter ride draws to its close, a feeling of depression, almost of discouragement, so few are the settlements, so desolate seems all Nature. They see the single line of rails, without a branch or feeder in the mighty expanse from Chelliabinsk to Irkutsk, save for the stub put in for the ungenerous outlanders of unlucky Tomsk. They calculate that for a territory forty times the size of the British Isles, and one and a half times as large as all Europe, the inadequacy of a railroad less in total mileage than the Chicago, Milwaukee and St. Paul, is manifest. Statistically-informed bankers sometimes shrug their shoulders at the mention of the Trans-Siberian. “Every year a deficit,” they say. “Gross earnings but twenty-four million roubles,--one sixth of the Canadian Pacific Railway; one tenth of the Southern Railway. _Hudoo_ (bad)!” One hears expressed not infrequently in Russia the opinion that the railway is a sacrifice justified politically by Russia’s need for a link to the Pacific, but ineffectual to secure prosperity and advancement to the isolated land of mid-Siberia. It is deemed, like the Pyramids, a monument to colossal effort and achievement but of little service to mankind.

Their statistics are correct. But it is to the greater honor of the road that much which it has accomplished will never appear in credits on the account-sheets. Where the white stations of the Siberian Railway stand now were once the wooden prison-pens with their guarded stockades. Murderers and priests, forgers, profligates, and university professors, highway robbers and privy councilors, all together have tramped this way. It is its past from which the railroad has raised Siberia, the past of neglect and exile that this steam civilizer has banished to the far Yakutsk.

Closer study gives, too, a better appreciation of the railroad’s economic significance. The line holds a strategic position as truly as does the Panama Canal. Though in Siberia proper there is the enormous area of nearly five million square miles, so much of this is in Arctic tundra, impassable swamp, forest, or barren steppe, that the really habitable and arable land narrows down to a tenth of this, which lies in general between the parallels of 55° and 58° 30’ north, and is contained within a belt some thirty-five hundred miles long and two hundred to two hundred and fifty miles broad.

When it is noted that the tillable area of one hundred and ninety-two thousand square miles in Tobolsk and Tomsk, mostly along the Obi System, the stretch of twenty thousand miles in the steppe, and that of one hundred thousand in the Yeneseik and Irkutsk governments of eastern Siberia, are all in immediate proximity to the railroad, whose course is generally along the 55th parallel, the economic value of Russia’s great enterprise takes a different perspective.

Its vantage is still more emphasized when the element of the north and south watercourses is considered. One after another the great Siberian rivers are crossed,--in the Tobolsk Gobernia, the Tobol, the Ishim, the Irtish; in the Tomsk Gobernia, the Obi and the Tom; in Yeneseik, the Yenesei; in Irkutsk, the Angara. Each of these reaches far up into the agricultural zone that lies north of the

railroad, bringing the harvests to its cars by the cheap unfettered water-avenues. Thus, to the part of Siberia that is capable of extensive development, the railroad is even now in a position to give great aid.

It is from such natural factors as these, not from financiers' figures, that one must weigh the potentiality of this great line. Its direct value is enormous, its indirect commercial services greater yet. It may best be compared to a mighty river system such as that of the Mississippi. The latter's traffic has never directly returned a dollar of the millions that have gone to maintaining its levees and training-walls and channels. Yet indirectly the return and the value, as an asset to the American people, are so great as to be incalculable. From its controlling position in relation to the cultivatable land and the interior watercourses of Central Siberia, as well as in relation to the far eastern artery, the Russian railway is an empire-builder as important as has been the Nile.

The results already achieved are noteworthy. The city of Omsk, where the railroad and the Irtish River lines meet, has risen from a population of thirty-seven thousand in 1897 to seventy thousand in 1908. Further east, Stretensk has sprung from a town of two thousand people ten years ago to over twelve thousand to-day. Irkutsk has climbed from sixty to over eighty thousand since the railroad opened.

[Illustration: ISLAND OF KALTIGEI VILLAGE OF LISTVIANITCHNOE LAKE BAIKAL]

The rural population has increased even as that of the cities. At the beginning of the seventeenth century, all Siberia contained but two hundred and thirty thousand souls; at the end of the eighteenth, one million five hundred thousand; at the end of the nineteenth, five million. Now, with the railroad-induced immigration, it approaches the seven million mark. The Steppe Government alone has risen in fifty years from five hundred thousand to one million five hundred thousand, and the Tomsk from seven hundred thousand to two million five hundred thousand.

More in importance than its present utility is the fact that the railway holds the key to Siberia's future. The arable territory of the belt is equal to that of Michigan, Wisconsin, Minnesota, Ohio, Indiana, Illinois, Iowa, Missouri, Kansas, Nebraska, and the Dakotas combined. This land is generally well-watered, in a climate suitable to grain-raising, and it is, as has been shown, in its whole extent, adjacent to river and rail transportation.

While such farming districts of the United States have some fifty inhabitants to the square mile, the most densely populated gobernia, Tomsk, has but six, and the Yeneseik but six tenths of one.

An immense further area will yield to clearing and to irrigation, as has been demonstrated in the great results secured from five hundred versts of canals in the Barbara Steppe. Coal and iron are available in many places, and timber in the greatest abundance grows in the northern district.

From a summary of these elements one may glean an idea of the Colossus sleeping beneath these snows. At a normal rate of increase, fifty million souls should populate Siberia at the close of the twentieth century. The agency of their coming and existing will be primarily the line of rails across the continent. Despite the eight hundred million roubles expended, with only far-off hopes of profit, the faulty road-bed, the light rails, the steep grades, and crawling trains, the glory of Russia is still "The Great Siberian Railway."

III

IN IRKUTSK

The train pulls slowly up to the white station-house at Irkutsk. A swarm of porters, _nasilchiks_, white-aproned, with peaked hats, and big, numbered arm-tags, invade the carriage. They seize each piece of luggage and run with it somewhere into the crowd outside. You, encumbered with your heavy coat, laboriously follow. Irkutsk station, more than any previous one, is crowded with passengers and Cossack guards. Train officials are shouting instructions, and every few paces a sentry is standing his silent watch. This is the transfer entrepôt for all through traffic, as well as the depôt for the largest and most important city of Siberia.

Threading the press on the platform, you struggle with the outgoing human current, and in time reach the big waiting-room of the first class. It likewise is crowded with a mass of people, and its floor is cumbered with heaping mounds of baggage. One of these hillocks is constructed from your impedimenta, which are being guarded now by a porter, apparently the residuary legatee of the half-dozen original competitors within the car. The man takes the long document that witnesses your claim to two trunks, and departs. Upon you in turn devolves sentry duty for the interminable time during which those trunks are being culled out from the

baggage-car.

It is an exasperating wait, but the fundamental rule for Russian traveling is, “never separate from the baggage.” The parcel-room here at Irkutsk held for six months a suit-case left by a friend to be sent to this traveler. The officials would not give it up to its owner or to any person save the forwarder, though he, oblivious to sequels, had gone on to San Francisco.

Like the rest, now, you camp, with the baggage in front of you, on the waiting-room floor. It is a very country fair, this station. At the far end is a big stand crowded with dishes, on which are cold meats, potato salad, heaps of fruit and cakes, sections of fish from which one may cut his own slices, boxes of chocolates, and cigarettes. All are piled up in heaping profusion. One can get a glass of vodka and eat of the _zakuska_ dishes free, or while waiting he may buy a meal of surprisingly ample quantity and good quality at the long tables that run down the centre of the room. Most of the Russians order a glass of tea, and with it in hand sit down till such indefinite future time as the luggage situation shall unroll itself.

We move our baggage and join the tea caravan. Across the table is a slight, brown-faced man, with an enormous black astrakan cape falling to his ankles, and wearing a jauntily perched astrakan cap on his head. “One of the Cossack settlers,” a friend from the train remarks. Beyond are half a dozen tired-looking women, with dark-gray shawls over their heads. Near them are men with close-fitting _shubas_, or snugly-belted sheepskin coats, fur inside, and rough-tanned black leather outside. Beside the lunch-stand are a couple of young men with huge bearskin caps, short coats, and high leather boots tucked into fleece-lined overshoes.

A general at one of the little side tables is talking volubly to a plump dame with furs, which are attracting envy from many sides. The lady merely nods between puffs of her cigarette, and sips her tea. A large fat merchant waddles past, wrapped in a paletot made of the glistening silvery skin of the Baikal seal. The room is stifling, full of smoke, and crowded with people. Yet no one seems to feel the discomfort, even to the extent of taking off the heavy outer coats, which, with the thermometer at twenty degrees below zero, they have worn on the sleigh-ride in, from across the river.

Your friends of the train, save those whose possessions were comprised in their multitudinous valises, are all here, fur-coated likewise and sipping tea, waiting, without a thought of impatience, for the baggage to be brought out.

At last appears your _nasilchik_. “They are got,” he cries, and balances about himself, one by one, your half-dozen pieces of luggage. Through the noisy, gesticulating, thronging passengers and heaped belongings, he shoulders and squirms a way to the door and into the anteroom.

A couple of soldiers are good-naturedly hustling out, from the third-class waiting-room opposite, a little leather-jacketed and very dirty mujik.

“I did not owe seven kopecks. I cross myself. I am not a Jew,” he loudly proclaims.

“_Nietchevo_,” says the soldier. “Out with him just the same!” The peasants and crowd loafing alongside grin appreciatingly, as the mujik is escorted, collar-held, through the great doors.

The porter and yourself follow. A plunging line of sleighs, backed up against the outer platform of the station, extends far up and down the road. Their _isvoschiks_, leaning back, are shouting for fares. In sight are your two trunks. “How much to the Métropole?” you call. The legal fare across the river to the hotel is a rouble, but the Governor-General of eastern Siberia couldn’t tell how much it would be if you didn’t bargain beforehand. “_Piat rubla!_” “_tree rubla!_” come hurtling from all sides.

It is for you to walk down the line calling in the vernacular, “fifty, seventy kopecks!” One of the drivers will eventually shout a fare which you feel able to allow, and the porter, who has been watching the bargaining process with keen interest, gives him the two trunks. The _isvoschik_ retires then behind the stormy hiring-line, and you renew the process for a second vehicle. The sleighs are just big enough for one person to occupy comfortably. Two can squeeze in if they be thin enough or economically minded. But a second sleigh is needed now for the hand-baggage, and a third for one’s self. At length the arrangement is completed. The porter bows low at the donation of fifty kopecks, “for vodka”; then, “Go ahead! all ready!” you call, and with a flourish the procession of sleighs dashes out of the station purlieus.

The road to the town mounts first a low hill parallel to the river. As the horses climb toward its crest the panorama of the city and stream, hidden previously by the railroad structures, unrolls. Like a great band of white, the frozen Angara sweeps to the left and right. Beyond it stand out boldly the clustered domes of the cathedral, their surmounting crucifixes glittering in the sunlight. At your feet are the sections of the pontoon bridge, which in summer spans the river but in autumn is disconnected, the parts being moored

to the shore, lest the drifting ice from partly frozen Baikal cut and destroy their woodwork.

A dark streak crosses the frozen river, with dots moving, as small apparently as running ants. The deceptive snow has made the distance seem much less than it is in reality. The streak is a road, and the seeming insects are the sleighs that pass and repass on the frozen river-trail. Between scattered wooden houses our cavalcade rides down to the bank, and at length onto the smooth white sheet. It is like skating. The big horses on our sleigh are imported from Russia, and trot splendidly, overtaking one after another of the citizens with their little shaggy Siberian ponies. The heaped snow is on either side. The cold air is bracing, almost welcome, until it begins to eat its way in.

It is a fair drive, this, across the river--a full verst to the northern bank. We mount the incline that leads up the slope, and come to the first log houses of the poorer quarter of Irkutsk town. Gaunt dogs bark feebly, and slink away on either side. The street is almost deserted; the houses give no sign of life.

Suddenly we come into a square crowded with people, gay with life and motion, and motley in colors. It fairly buzzes with talk and cries and chaffering. Low-built booths face every side of the open _piazza_. We catch a glimpse of one stocked with hardware. Opposite it stands a little shrine within which are dimly visible pictured saints and the Madonna, before which are scores of burning tapers. Our _isvoschik_ takes off his hat as he drives past, and reverently makes the sign of the cross. He crosses himself also as he passes the white church of St. Nicholas with its green roofs and gilded crosses, and he removes his cap to the long-haired and dark-robed pope that he meets, for the Siberian pays much reverence to his Church.

[Illustration: THE ANGARA RIVER THE CATHEDRAL IRKUTSK]

The residences improve from the log cabins of the outskirts, and grow into the two-storied whitewashed structures of the main thoroughfares. The streets also have an interesting procession of people. The big troika of some high official glides past, with coal-black horses and a coachman padded out into a liveried Santa Claus, after the style of St. Petersburg. Officers of the garrison sweep by in their light-gray overcoats. Shoals of sleighs and sledges are going to and fro. At almost every corner, armed with a sabre and revolver, stands a police officer.

As one drives along he reads the Russian letters on the placards and the names on the stores. Many here are Hebrew, for the Siberians of the cities are more tolerant than their European cousins. Irkutsk has a very large and prosperous Jewish merchant community, and sent her Dr. Mendelberg to the Duma. Irkutsk has had its representation cut down, they say, _post hoc_,--perhaps _propter hoc_.

The driver, who has kept his horses at a moderate trot from the station through the town, suddenly cries out to them, and swings and snaps his lash till they break into a gallop. “We always come in handsomely,” says the city native who is with you, as the sleigh pulls up triumphantly at the door of the Hôtel Métropole.

A swarm of attendants greet you at the portal, a tall uniformed concierge, half a dozen aproned porters, a waiter or two, a page, and behind them the Hebraic Hazan, our host. Each porter seizes a parcel and the concierge leaves his post by the front door to lead the procession up the broad red-carpeted stairway. With a rattle of keys he swings open the door to a salon big enough to give a ball in, and whose ceiling is six good feet above one’s head. The average New York flat would rattle around in it. The concierge advances to its centre and bows. Then he goes on through to another room, almost its duplicate in size, with a forlorn-looking washstand and a screen across one corner.

“But the bedroom, where do we sleep?” you ask.

“_Sdiece, gaspadine_,” he says, “right here”; and he conducts you to the screen.

Raised about eighteen inches above the floor is a little wooden platform-like structure, about the size of a cigar-shop showcase. A dingy mattress is rolled up at one end of it. As you ruefully feel its straw texture and survey the planks which it is to cover, the hotel-keeper pushes in to tell you that sheets will be put on at once if the _gaspadine_ has not his own. “_Chass! Chass!_ If only the rooms suit the _gaspadine_, everything will be arranged.”

The porters silently deposit their loads and depart with their twenty kopecks each. The manager goes out, doubtless to gather his sheets. Only the concierge stays expectant after he has received his tribute. You throw your heavy overcoat over one of the armchairs and begin to open some of the bags. The concierge still stays and looks on. You begin to segregate laundry, and locate brushes and tooth-powder. The concierge still stays and looks on. You get out some slippers which are an improvement upon the

heavy snow-boots. The concierge still lingers.

“The room is accepted,” you say finally.

“Yes, yes,” he answers. “_Haracho_, but for the police, I want, please, your passport.”

To show your passport, true enough, is no more of an incident than to take out your handkerchief. But to be obliged before you have been ten minutes in a place to produce a paper for the police telling of your age and infirmities, the color of your eyes, the number of your arms and legs and children, seems tiresome.

“Must all give in their passports?” you inquire.

“All, all,” he answers. “I am punished if one person stays here overnight without showing it.”

He takes the document, visibly impressed with its flying eagle and the big red seal, and bows his way out.

Now one can stroll around one’s suite and take in some of the details. There are electric lights with clusters of globes in the big pendant electrolier of the parlor, and drop-lamps for the massive writing-desk in the corner! The armchair by the high-silled window is a good place to read in. Too bad one cannot look out on the shuttling sleighs of the street below, but the cold has thickly frosted the double windows. Here is a big sofa, plush-covered, and half a dozen armchairs surround the polished table, whose top is scarred with a multitude of rings--from the hot tea-glasses, one deduces.

Mentioning tea, why not have some? There ought to be a bell somewhere. Unfortunately there is not a bell. In looking for it one finds that Siberian housekeeping does not include any dusting of the heavy red hangings which flank the doors and windows. An imperious cry resounds in the corridor. “_Chelaviek!_” It is followed by a patter of footsteps. So this then is the custom of the country. You open the door, and in the tone described in books upon elocution as “hortatory,” cry out into the dim distances of the corridor, “_Samovar, chai!_” Somewhere down the line a voice answers, “_Chass, chass!_” and you retire to wait and hope.

Curiously battered the furniture looks when you inspect it closely. Here and there a flake is chipped away from the varnish, and cuts or dents show in the paint. Have sabre fights, perhaps, taken place here, or raids on assembling revolutionists? Certainly in the generations of occupants, life has been, in some fashion, tumultuous.

There is a fumbling at the door-knob, and, without any preliminary knocking, a waiter comes in with a nickel samovar, an empty teapot, and a glass. He puts them down on the battered table and walks out. The big kettle hums away pleasantly as the red charcoal in its hollow interior glows from the upward draft. The preparations seem all made, save for the tea. Perhaps the _chelaviek_ has gone to get it. You let your eye rove around to the little ikon far up in the corner, and the sleighing and wolf-shooting etchings on the walls. But after a time this becomes tiresome. Has the secret gendarmerie descended on the waiter among his teapots and trays? Has he forgotten the matter entirely, or what? The corridor-call seems to be the only recourse. Once again you go out. “_Chelaviek!_” and from some region he comes trotting up.

“Where is that tea?”

“Oh, _chai_,” he says, illumined. “Has the _gaspadine_ not his own?”

“Most decidedly the _gaspadine_ has not his own,” you retort. “The _gaspadine_ does not carry pillow-shams or bales with him. He is not a draper’s establishment or a grocer’s store.”

“_Nietchevo_,” says the waiter, amiably; and runs off, to return with a saucer of tea-leaves, and another containing half a dozen lumps of sugar.

“Your pardon, generally the _gaspadines_ have their own”; and he leaves you to the brew and your meditations.

Well, it is pleasant, after a long train-ride, to stretch out in a big, if battered, armchair, and sip glasses of anything hot. The little teapot, full of a very strong decoction, is perched on the top of the samovar over its chimney. For a fresh glass you pour out a half-inch of the strong essence, throw in the sugar, and from the samovar’s spigot fill the glass with hot water. It is thus just the strength you personally prefer, and always hot. The samovar, by a judicious regulation of the draft, can be kept for hours exactly at the boil. It is a fine institution, but cannot be transplanted to a country where hot charcoal embers are not constantly available.

Comfortably ensconced and sipping one's tea, one can leisurely, Russian fashion, think of the most amusing method of passing the time. It is getting on toward evening; for the day fades early here. To-morrow is soon enough to look at things and distribute letters of introduction. The beverage has also blighted the appetite. Perhaps a light supper and an early couch would be wise. The latter in the far room looks singularly unpromising, but, "_Nietchevo!_" It is rather early for dinner or supper, but what of that? As an elusive New York politician used to say to each of the office-seekers who came to ask his influence for nominations, "If you want it, there is no reason why you should not have it." We will try another summons of the waiter.

Up he comes with the bill of fare printed in Russian and alleged French.

Perhaps some eggs would be good. You decide upon them to begin with, and you will have them poached.

"_Gaspadine_," he says, "the eggs to-day cannot be poached. Will you not have an omelette instead?"

On second thoughts we will not have eggs at all this time; we will have a sterlet, a small steak, and a compote. He goes off to the nether regions again. A long time passes, but at length he returns with the sterlet, its chisel-shaped nose piercing its tail in true Siberian style. White creamy butter and Franzoski kleb, white bread, round out the course. The steak is excellent and the canned fruit is satisfying, eaten beside the singing samovar in the great room of the main hotel of Irkutsk. Half a dozen letters pass the next hours until it is time to sleep. They are written on the big desk beneath the drop-light, with a glass of tea at one's elbow in warm cosy comfort.

The place is rather warm, and without any apparent source of heat, for there are no registers or gratings of obvious instrumentality. A search of elimination, like the game in which one is warm, warmer, very hot, leads at length to a rounded corner of porcelain built into the wall, of which only a curved segment shows in an angle of the room. Further inspection reveals that it is a big cylindrical stove fed by somebody in the hallway, and so arranged as to warm two adjoining rooms.

In mitigation of the fire-tender's zeal, we decide to open a window. Perhaps with an hydraulic jack this might be possible; but to manual labor it is not. A single pane of the inner window, however, swings back, and then we can open a similar pane in the outer window, leaving a hole as big as the port of a ship. It is sufficient in this weather. Some further corridor-shouting, produces, in due time, sheets and blankets, and presently we lie down on the straw mattress in the little wooden-bottomed box called a bed. "_Spacoine notche_," the attendant calls, and without trace of irony.

It is one thing to go to bed, another to sleep. Tales are told of powder-circled couches which the invaders, surmounting these ramparts by climbing walls, dropped upon from above. There is a legend that there are some people whom they do not bite. "_Nietchevo!_" Is it not Irkutsk, the Paris of Siberia? Why then complain of parasites?

Furthermore, a brass band has started up somewhere in the immediate neighborhood the tune of _Viens poupoule!_ to which there echoes a popular accompaniment of tapped glasses and stamping feet. Perhaps one had better get up and see things after all,--"Needs must when the Devil drives." We dress again. An exploring expedition reveals the big dining-room on the floor below full to the doors with uniformed officers, long-haired students, and assorted civilians. All are drinking and smoking. On a stage at one end of the room thirty short-skirted damsels are singing and dancing in chorus, to the great approval of the audience. As the curtain rolls down on an act, the _ci-devant_ dancers descend to their friends on the floor. Corks pop, and sweet champagne flows. The call goes up for "_Papirose!_" and more cigarettes and more bottles come thick and fast.

Soon there is an air of subdued expectancy, and eager looks are directed to the curtain. Somebody near by leans close and whispers for your enlightenment, "All-black man!" Out comes an old Southern Negro, who sings to the wondering Russians a Slavonic version of the "Suwanee River," between verses delivering himself, with many a flourish, of a clog-dance. Johnson is the man's name. How he drifted so far from Charleston he hardly knows himself. He followed the music-halls to 'Frisco, and somebody, for whom he "has a razor ready," told him he would make his fortune in Vladivostok. He kept getting further and further into the interior, picking up the language as he went, and turning his songs into the vernacular. Poor chap, the pathos he puts into the "Suwanee River"! He is thinking, in frozen Irkutsk, of the old Carolina homestead, and is singing and dancing his way back.

A girl in peasant dress takes the stage after "Sambo." She is singing some song that is running its course across northern Asia. The lassies at the tables and the men join in. Glasses clink and heels tap. The miners who have made their stake, the prospectors who hope to, the sable-merchants of the Yakutsk, the wool-dealers from Mongolia, all meet here as the first place where the rigors of the hinterland can be compensated. It is very gay--very, very gay.

In the years after the ukase of Paul I, ordering that all officers who had made themselves notorious for lack of education or training should be sent to the Siberian garrisons, it may be imagined what a Gomorrah grew up under the Russian banners. Modern celebrations are by comparison mild and temperate, as the cold beyond these double windows is mild and temperate to that outside the Tunguses' huts, in the Yakutsk Province. But it is fairly impressive, nevertheless.

Even in a Siberian hotel, the world goes to bed sometime. By four o'clock the music has stopped, and the traveler is tired enough to sleep on even the populous plank-bottomed bed. Thus do all things work together to weave the "web of life."

It is nearing noon when one wakes to eat a combination of breakfast and lunch, and plan for the day. The Post-Office and the Bank are the first material objectives. One must register so that mail may be delivered. We go down and join two companions of the road. With careful directions from the porter, the party prepares for the half-mile walk to the Post-Office. The preliminaries are formidable in themselves. First the felt goloshes must be pulled over the shoes; then the big fur overcoat must be swung on and carefully buttoned down its length. Finally a fur cap, like a grenadier's, with ear-flaps is tied, and great fleece-lined gloves are donned. The droshky-drivers assembled before the hotel seem to take it as an insult to their profession that we elect to walk, and two or three follow along outside the curb until the group reaches the corner and turns into the main street, Bolshoiskaia.

[Illustration: A CHAPEL BOLSHOISKAIA IN IRKUTSK]

There is an air of placid quiescence at this noon hour. The policeman at the nearest corner is ruminatingly handling his sabre-hilt, and watching the sleighs go by. Here and there a woman, with the ubiquitous gray shawl over her head, passes, with a preoccupied air. Sheepskin-clad mujiks are driving along, with sledge-loads of firewood or stiffly-frozen carcasses, on their way to the bazaar markets. The shop-windows attract our gaze. Here is one with the word "_Apteka_" over the door, which is to say, Apothecary. Benches are set in front of it, on which one may sit and watch the people pass, as in the chairs before a New England country tavern. Further along is a solidly built white department store, the Warsawski Magazine, wherein one can get all manner of apparel,--shawls of the latest Irkutsk pattern, towels and soap, and--most important--blankets for the trip into the interior. We stroll in for a moment. An individual looking like a stalwart Chinaman, with long braided queue, shoulders his way past us to buy some cloth.

"He is a Buriat of the tribe north of Irkutsk," explains one of the shop-girls, very close herself in type to those seen at Wanamaker's in Manhattan.

Near-by the imposing magazine is a low one-story booth occupied by a watchmaker. Beyond that is a walled enclosure with lofty gates, as befits a school. Still further is the yellow and green sign of a government liquor-_traktir_. The name is said to be derived from the French word _traiteur_, which was current in the days when Napoleon and Bourrienne were planning conquests in their Parisian poverty.

As we turn up a side street, the shops for the poorer people appear. Gaudy pictures, of packages of tea, vegetables, and sugar-loaves, illuminate the walls, to tell the unlettered that groceries are sold within. Saws and hammers and vises are painted on the walls of the hardware-shops. Loaves of bread, crescent rolls, and rococo wedding-cakes decorate a bakery; boots and high-heeled slippers, a shoemaker's booth. The street is an open-air gallery of rude frescoes.

Presently we come to residences, some of cement-covered brick, with high enclosing whitewashed walls and iron gates, some wooden, with their rough-hewn logs unpainted save for the brilliant white sills and window-frames.

At length, far from the town's busy district, the Post-Office is reached. The building is thronged. Two soldiers are loading their saddle-bags with the mail for the regiment. Women are collecting money-orders. A crowd waits at the window of the girl who sells stamps. In rushing industry she makes the calculating beads of her abacus fly across the wires. Everybody is far too occupied to register a voyageur's name,--excepting always the half-dozen soldiers posted in different parts of the room and leaning stolidly upon their bayonets. We venture to ask one of them which is the registry window.

"_Russisch verstehe ich nicht_," is the answer.

A Siberian post-guard knowing no Russian and answering in German seems extraordinary.

"Where are you from?" we inquire in his native tongue.

"Courland," he answers,--"Courland by the Baltic."

This city of Irkutsk gave trouble in 1905. If it gives trouble again, the garrison will be safe.

The registering at length is done and we turn to go out. A tattered figure, bearded and haggard, with rags bound on his feet, opens the outer door.

“Will the _gaspadine_ help a man get back to Russia?”

Your companion looks closely at him.

“A convict! very bad people.” He adds: “There is a murder every day here, and one cannot safely go out at night. Very bad men!”

With the contradictory charity that is so typical of the Russian, he fumbles in his pocket and gives the unfortunate a fifty-kopeck piece.

We go now to the great market-place and the bazaars. Here where we enter is a row of hardware-shops. In the first booth a string of kettles hangs down, and knives, spoons, candlesticks, and hammers are suspended so as to catch the eye. The proprietor stands outside, chatting with a passer-by and the tenant of the adjoining booth. Further on are stationers, with tables of cheap-covered books. The wall of one is decked with chromos of galloping Cossacks, led by a long-haired pope with a crucifix. The soldiers are sabring fleeing Japanese, and red blood is lavishly provided. On the opposite wall are glittering brass and silver ikons, and lithographs of ancient martyrdom.

Row upon row of red felt boots hang in the next line of booths, and in still another--the wooden-ware bazaar--are bowls and spoons, and platters of high and low degree. Further on a dozen women are grouped around one of their class, who is bargaining for a huge forequarter of beef, a full _pud_ weight by the big lever scales that are balancing it.

“_Dorogo! dorogo!_” (Too dear, too dear!) she cries. “I will give eight kopecks a pound.”

The market-woman protests that she will be beggared at less than eleven kopecks.

A half-_sotnia_ of little Buriat Cossacks come riding by, clad in their puffy leather _shubas_. Yellow-topped fur caps are their only uniform garment, and across their backs are hung the carbines. They make merry at the haggling women. Two swing off their shaggy ponies, and begin in turn to bargain in broken Russian for some paper-wrapped sweetmeats. They close the deal finally, tuck these away, toss themselves back into position, and ride off. Further along, half a dozen men cluster around a fur-cap seller. He is a merry fellow, and there is much noise and banter and gossiping. Such is the bazaar, the Forum of old Rome set down in a Siberian city.

[Illustration: THE BAZAAR, IRKUTSK]

A short further stroll, and the party is at your other objective, the Bank. You take leave of the rest and enter. At the door, a grandly uniformed porter helps you off with the outer husk of furs, and motions you into the outer office, with its half-dozen clerks bending over sloping desks. One of these takes your card, and returning leads the way to a capacious sitting-room, with armchairs scattered here and there, pictures on the wall, magazines of many nations on the centre table. The American typewriter, which alone betrays that this is an office, is on a little table at one side. A tall military-looking man, gray-mustached and grave in manner, is seated beside the window reading some documents. He rises as you enter, and greets you, and for some minutes the conversation in French is upon general themes. Presently you go down into a side pocket and get out letters of introduction. One is from the Petersburg headquarters. He looks at the signature--Ignatieff.

“You are his friend?” The polished worldliness falls away as a cloak that is thrown off. “Splendid!” he says. “Welcome to our city. We must have tea.” He pushes a bell, and a page, red-bloused and wearing brightly polished jack-boots, appears. “_Chai_, Alexis,” he orders. “And how did you leave Ignatieff?” he begins eagerly. “Does he still drive his black stallions? It is two years that I have not seen him. When I was in Petersburg last winter, he was in Paris, and when I was in Paris, he was at Nice. One is very separated from his friends here. One might as well be a convict.”

You answer all his questions, and begin to feel as if you were at a little family party. Presently, in the midst of the double conversation,--for the Russians seem to talk and listen at the same time,--the boy comes in with a big samovar, and the other accompaniments. The banker makes the brew in the china pot. From this each of us serves himself as the compound conversation moves on.

“You have not yet seen the sights of Irkutsk?” he observes at last. “I will get my sleigh and show you around when we have finished.”

“It is the middle of the day. I cannot break into your work like that,” you protest.

But he rings a bell for the red-jacketed boy. “Order my sleigh.--We have the finest city in Siberia,” he continues; “eighty thousand people now, and growing always. And trade has come with the railroad as we had not dreamed before. In the days when they used to bring the tea overland from Kiahta, the sledges from Baikal would carry as many as five thousand bales daily. We thought when this began to be shipped through by the railroad that it would hurt the city. But there was so much other traffic that the loss was hardly felt.”

“The sleigh is ready,” the boy announces.

“May I have the honor?” he says, with his easy grace.

He leads the way to the coat-rack, and is received with the deepest bows by the uniformed worthy, who solicitously helps him on with his coat and overshoes. Then with a stereotyped motion the man holds out his hand for the tip. Though this servant is at the door of the banker’s own office and presumably upon his pay-roll, the incessant tribute is his perquisite. It is usual throughout Siberia for wealthy Russians to scatter small silver everywhere along their path--to friends’ servants, to house-porters, to beggars on the street. The most profuse miscellaneous generosity prevails. Riding to-day with the Russian banker is like watching the progress of a mediæval prince dispensing his largesse.

At the entrance to the bank is the sleigh, skeleton-framed and high-built, unlike most of the sleighs of Siberia. Three big black horses, with the snake-like Arab head that characterizes the best Orloff strains, are hitched to it, troika-fashion, the centre horse under a big bow yoke, the outside animals running free. The coachman has the square pillow-hat, and the enormous wadded corpulence of Jehu elegance.

It is an interesting ride in which we move slowly up the Bolshoiskaia, receiving, so far as the banker is concerned, neighborly greetings from most of the sleigh-riders, and respectful salutes from the foot-passers on the sidewalks. A nice social distinction our host draws in returning the formal salute for uniformed officials, the cordial wave of the hand for intimate friends, a nod for the humbler acquaintances: but none go unrecognized.

Something like the Roman’s idea of showing his city by turns up and down the Corso, is this Siberian’s. We do halt, however, and look at the big Opera House and the Geographical Society’s Museum and the many-domed Cathedral,--buildings which in no city would be other than sources of satisfaction. After an hour of driving in the piercing cold, one’s conscience begins to prick. The banker, even though absent from his affairs, does not appear to feel either business or atmosphere. At length we are brought at a gallop to the doorstep of the hotel.

“To-night we dine at eight. Adieu.” With a bow he draws the bearskin robes about him, and the black horses bear him swiftly around the corner.

An acquaintance from the train is in the hallway as you climb stiffly up the steps.

“Has the drive been a bit cold?” he asks. “Come in and have a _stakan_ of vodka.”

“Is that not rather heady for a between-meal tipple?” you suggest.

“This is Siberia. When you run with the wolves, you must cry like a wolf,--but tea, too, is good.”

You mount the stairs together, to the scene of last night’s orgy, and order a couple of glasses of tea.

It is a strange anticlimax to find the room so deserted. At three this morning it was a good imitation of the traditional “Maxim’s.” At four in the afternoon it is simply a crude wooden hall, with the stiff-backed, plush-seated chairs ranged in bourgeois regularity at the discreetly covered tables. Only the shuffle of somebody practicing a new step on the stage behind the curtains suggests the double life of this innocent-looking hotel dining-room.

A couple of glasses of tea attack the cold in strategic fashion, from the inside, and are better than the external reheating method. We sip in silence for a while.

“I am going to drive over to the Banno and have a Russian bath,” observes your companion. “I do not like the tin tub they bring around here at the hotel. Are you impelled to come along?”

“Is there attendance and room for two? I’m not minded to sit around and wait.”

“Room for five hundred,” he says, with a long sweep of the hand. “Everybody goes there. It is one of the institutions of the city.”

As you are now warm enough to consider a further drive, you go down to assist in bargaining for a sleigh to make the tour to and from the Banno.

A big brick building a verst or so away, with a number of private equipages and a stand for public sleighs and droshkys, is our destination. A beggar-woman opens the double doors and gets her service percentage from each passer.

“How much is given in this part of the world to beggars!” you remark.

The Russian smiles. “It is a part of religion to give. At every big family affair,--a wedding, a christening, a funeral,--we distribute money and gifts to the poor.”

In the entresol of the bath-house, a big tiled anteroom, there are marble-topped tables, around which men and women are smoking and reading papers. One can dine here, even; but this comes after the bath. A ticket at the _kontora_ gives, for a rouble, the privilege of a preliminary boiling and a flaying by one of the naked attendants. A start is made by washing you with infinite thoroughness, section by section, the attendant continuing on each spot until told to stop or advance to the next. An unfortunate foreigner, in Irkutsk, had his head shampooed seven times in succession before he could recall the cabalistic word necessary to direct the man’s attention elsewhere.

One is scrubbed and rinsed, and is then conducted up onto a wooden platform, running along under the ceiling. Here, while the first inquisitioner dashes water on a steamer-oven below, the second scrapes the victim with new pine branches. One remembers an Irkutsk Russian bath at least as long as the smarting and the cold he gets from it endure.

Back at the hotel one can dig out his rather crumpled dress-suit in preparation for the evening’s entertainment. Later, he gathers in another sleigh, and sets out for the home of the banker.

In Irkutsk nobody relies on house-numbers to find his way. Even Moscow has not yet advanced to this refinement of civilization. If the driver does not know the route, he stops to ask passers-by, “Where is So-and-So’s house?” Again and again you are taken to the abode of somebody else with a name more or less similar. Then the driver will say, quite nonchalantly, “_Nietchevo!_”--ask the next person he encounters for directions, and start anew. You leave abundant margin of time, and usually arrive sooner or later.

Our host of to-night is, happily, well known throughout the city. So the driver whips up to a gallop and rushes down the snowy streets. It is not a long ride to the big arched doorway of the white two-storied plaster-covered house, in front of which the driver pulls up with a flourish. You ring a bell at the side of the door and wait. The _isvoschik_ has taken a station beside the curb, has folded his arms, and is nodding on the box, apparently prepared to camp there indefinitely. “Eleven o’clock, return,” you say. “_Haracho!_” is his drowsy answer, given without moving. The horses have drooped their heads; they too are settled for repose. The tinkle of a piano comes from within, but minute after minute goes by, the bell unanswered, the _isvoschik_ immovable on his little seat. Other pulls of the bell are at last of avail: the door slowly opens. A final objurgation to the coachman that he is not wanted until eleven o’clock falls on sealed ears. You go in through the massive doorway.

In the antechamber a gray-bloused attendant helps you off with wraps and goloshes, then silently disappears through a rear door, leaving you standing there unannounced. The vestibule is cumbered with coats and hats on the wall-hooks, overshoes helter-skelter on the floor, and canes and umbrellas in the corner. It is like a clothing establishment. Beyond the curtained doorway on the right are lights, and the sound of the piano is louder. This seems the most promising direction for exploration, so--forward!

Beyond the portières is a splendidly lofty room, like that of an Italian palace, brilliantly lighted with electricity. Many-paned windows run high up, starting from the level of one’s breast, and long heavy hangings half-conceal them. To the right of the door is a mahogany grand piano, at which, oblivious of the world, the host is diligently thumping away at _Partant pour la Syrie!_ with inadvertent variations, singing carelessly as he plays. Beyond him, in an imposing armchair of German oak, like King Edward’s throne in the Abbey, is a lady, propped with many cushions. She is slender and darkly clad, and is conversing with a young man in uniform, who sits very straight on a dainty gilt chair of the Louis XVI epoch. A low lacquered table before them is gayly painted with

geisha girls and eaved pagodas. It holds a massive brass samovar encircled by a row of beautifully colored tea-tumblers of the sort that one sees on exhibition in the glass-factories which front the Grand Canal at Venice. The chorus comes from the banker at the piano:--

Amour à la plus belle; Honneur au plus vaillant.

[Illustration: THE ICE-BREAKER, YERMAK--LAKE BAIKAL]

There is no use of paltering and waiting to be announced, so we enter the room. The performer hears the steps on the polished floor and swings round on the stool. “Ah, voilà!” he says, and rises to introduce you to his wife.

“A moi le plaisir,” she says, smiling. “Mon frère, Ivan Semyonevich,” presenting you next to the young officer, who rises abruptly and clicks his heels as he takes your hand.

You are motioned to a replica of the little chair, and your host returns to his piano, this time to play with immense satisfaction in your honor a hazy memory of some bygone variety show: “There’ll be a hot time in the old town to-night.”

“A friend is very welcome,” says Madame Karetnikov, when he finishes. “We do not see many from the world here in Siberia.”

“The life, however, is interesting, is it not?”

“O monsieur, I, too, was interested at first, but there are so few people of the world here, and we see them all the time. C’est affreux! I give you a month to change that opinion.”

“You give a month, Irina; I give a week,” growls her brother.

“If it were not that we get away during the spring one would perish of ennui,” the hostess adds. “But Japan is not far. We go there or to Europe every year. Perhaps soon we shall get a transfer to another branch.”

“You bankers have hopes,” observes the brother, “but what of us poor officials of the Justice Department! We are chained to the bench like old galley-slaves, and all we get is three hundred roubles a month and a red button when we are seventy.”

As the macerated song floats anew from the piano, the hall-door opens and there is dimly visible in the anteroom a curious much-encumbered figure, with a gigantic sheepskin hat and short blue reefer coat. He divests himself of these, and of a long woolen inside muffler, and, brushing back his long hair, comes into the room. His blue tunic is resplendent with brass buttons and he wears jack-boots. A light down is growing upon his upper lip. He is nineteen or twenty.

“Good-day!” says our host, hailing him in English.

“Good-day, uncle!” he replies.

He presents himself before Madame Karetnikov, who holds out her hand, which he formally kisses.

“_Zdravstvouitie_, Valerian!” says the official, shaking the young man’s hand.

Then you are introduced with explanations.

“Valerian here is in his last year at the Irkutsk Realistic School, studying preparatory to engineering.”

The status of science in Siberia becomes the theme, and the newcomer infuses considerable local color into his pictures.

“Does the professor in drawing suit you now, Valerian?” the banker inquires presently. Then he adds to you: “They all went on strike because the old professor of drawing had a method they did not like. The authorities had to replace him before any of the students would go back.”

“The new professor respects our rights,” says Valerian soberly, not liking the levity of his elder.

Soon, from an adjoining room, come in the children of the host,--a very pretty girl of the age at which misses wear short dresses and braids; and a little boy of about eight. The boy very respectfully kisses his mother’s hand and is introduced to the stranger, but finds a superior attraction in his father at the piano.

The girl, Marie Pavlovna, sits down beside her cousin Valerian. Lacking the stock football amenities of a happier land, and half-embarrassed, half-superior in the status of a budding young man, Valerian is not much of a conversation-maker. Marie Pavlovna, too, is seen but not heard. She is evidently the typical product of the French system of sex-segregation and cloistered study, which keeps girls abnormally uninteresting until marriage, perhaps to make amends subsequently.

“I think we had better go in and eat. It is half-past eight,” says the host.

“Si tu veux,” replies his wife; and we stroll out into a big dining-room, at one end of which is a heavily-freighted oak sideboard.

As we approach this, the host opens a far door, and shouts down into the darkness:--

“Obeid, Dimitri.”

We turn to the _zakuska_ sideboard. The official reaches for the vodka-bottle, and the little silver egg-like glasses.

“Vodka will it be, or do you prefer cognac?”

The various guests choose their tipple. With the gulp of a mountaineer taking his moonshine, the banker swallows the twenty-year-old French brandy, of the sort that gourmets protractingly sip with their coffee. The little boy slips out to his particular region of the house. The hostess takes her seat at the foot of the table, and the gentlemen pass and repass, bringing her assorted _zakuska_ dishes as at a ball. Caviar from the Volga, Thon mariné from Calais, sprats from Hamburg, Columbia River salmon, are spread out and attacked by the rest of us, standing, free-lunch fashion. One by one the men finish and straggle to their places at the table.

Three menservants, with gray blouses and baggy silk trousers falling over their topboots, appear now, one with a huge tureen of bouillon, another with the little silver bowls, and a third with a plate of the _piroushkies_ that accompany the soup. Madame Karetnikov deals out the consommé for the whole table, and also for little Paul and his governess in some outside quarters. Every one begins to eat, without waiting for the hostess or for anybody else.

“It is hard work managing a big family like ours,” she allows, in reply to your question about the domestic problem. “We always have seven or eight, and one can never tell how many friends will come in to dine with us.”

She casts a solicitous eye over the table, to see that no one has been neglected, and then serves herself.

“One must keep the men well fed,” she observes. “Remember that, Marie, when you get married.”

Marie at the far end of the table nods assent.

“But you must not think of marrying until you are told,” adds the banker.

She nods assent to this, too.

“Don’t mind him, Marie,” says the official. “He thinks he is living in the time of the Seven Boyars. Take my advice. Pick out the man you want and go for him. You can’t fail.”

“Such ideas to put in a girl’s head!” says his sister, smiling.

The soup-course is nearly over, when suddenly the banker ejaculates, and jumps up to welcome some new arrivals.

“Ah, father!”

He runs to a sturdy benignant-looking old man, and kisses him on both his white-bearded cheeks, then does the same to the little old mother.

“Come in, come in; we are just beginning.”

At once the table is in a state of unstable equilibrium. The old lady is steered to a chair at the head, and the rest are pushed along to make room. The father makes his way, under similar escort, in the direction of the vodka-bottle.

“No French brandy for me!” he says, and puts the fiery Russian liquid where it will do the most good. He, too, goes to the far end of the table.

The student tells in a low voice that the newcomer is a veteran of Sevastopol, was once the personal friend of Czar Alexander, the Liberator, and was decorated by him for gallantry at Plevna.

“What a splendid old Russian he is!” one thinks, noting all the kindliness and courtesy of his honored age, and the grip of a bear-trap in his hand. Yet there is an indescribable air of melancholy about him, as if a great sadness were being bravely and uncomplainingly faced. A remark from the hostess turns you to her.

“Father is one of the Colonization Commission. We are all very much interested in hearing about his discussions with the settlers!”

“Colonization for the settlers or for the exiles here?” you ask.

“It is the government assistance for the voluntary emigrants, not for the unfortunate ones.”

“But the latter must be a problem in themselves?”

Madame seems embarrassed.

The student leans over and in a low tone whispers: “His youngest son, the brother of Vladimir, is in hiding, is under sentence of death. They don’t speak of him here.”

“He has just come from the Governor,” adds Madame Karetnikov, “who is a great friend of his. The Governor has heard from Petersburg that they may bestow the cross of St. Stanislaus.”

“That is the autocracy here, which you do not know in your country,” adds the student, in a low voice. “He is an intimate friend of the Governor and two of his sons are officials, yet his last son is beyond pardon. The old man himself knows not where he is. Yet they decorate the father. He still believes in the Emperor.”

“Do not let my nephew talk politics to you,” says the hostess, rather anxiously.

Valerian is silent.

A supplementary tureen of soup makes its appearance, and the two newcomers are served with it. The rest of the party have advanced to boiled sturgeon, with a thin sauce, compensated by Russian Château Yquem from the Imperial domain in the Crimea. Roast beef follows the fish, with the old general and his wife at length even with the rest.

Then come duck and claret, and finally dessert and champagne. The toast of the evening is drunk to the old general, who brightens as the meal advances. In the big reception-room, Turkish coffee is brought, which is poured from the brazen ladle and served in exquisite little cups without handles.

“We got them in Damascus on one of our trips,” says the host.

Conversation goes round the table. The official is in eager talk with Madame Karetnikov about a common friend in a smart Petersburg regiment, who has got badly in debt.

“He ought to apply for a transfer to the Siberian service. The officers get more pay, and it costs less to live,” she is urging.

“But for Serge we must consider how much greater is the cost of champagne here,” retorts the official.

“We can marry him to Katinka, and make her father get him a promotion,” the sister suggests. “I think he ought to have left the army and gone into the contracting,--every contractor I know is as rich as sin and goes to Monte Carlo.”

So the conversation rambles on. Cigarettes are passed. The hostess will not have one.

“I used to smoke, but it is so common now,” she explains. “Every peasant’s wife hangs over her oven with a cigarette in her mouth. Even a vice cannot survive after it has become unfashionable.”

The host comes up to show you his curios.

“This Alpine scene is one of Segantini’s. We got it in Dresden before he had earned his repute. I am very proud of my wife’s discrimination. The statuettes are from a little sculptor in the Via Sistina in Rome. Rien d’extraordinaire. The vase came from the Imperial Palace in Peking. I bought it from a Cossack for fifty kopecks. I have been told it belongs to the Tsin Dynasty, and is better

than those they have in Petersburg Hermitage."

So you are shown the spoil of two continents in connoisseur purchases.

"Hardly to be suspected in Irkutsk," he allows, complacently.

Every year host and hostess visit the Riviera, taking a turn at Monte Carlo and Nice and Cannes. The banker speaks English, French, German, and Italian fluently, and half a dozen other languages passably. His wife acknowledges only French and Italian.

The conversation turns to the idealism of Pierre Loti's description of the road to Ispahan. The banker has followed this road himself, and he has a much less poetic memory of it. The veteran--his father--is not up in French or English, but he has a good knowledge of German left from academy times. In this language he tells of the old days of the serfs and of the Crimea. He talks with the kind frankness of age that does not need self-suppression to prompt respect. When the guests rise to leave, and the buoyancy of the entertainment is passed, his cloud comes back. His voice has just a touch of bitterness as he says good-bye.

"I am glad we can welcome to our country a man traveling for pleasure. So many who come are here under less pleasant auspices."

"_De svidania_," you say at last to everybody, and out you go into the midnight frost. The droshky-driver is still there waiting. He has slept since you entered, unmoving through the hours. "_Gastinitza_," you direct; and he drives to the hotel through the bleak starlit night.

Valerian comes a few days later to visit us, and volunteers to be our guide for Irkutsk.

"If I miss a few days at the Academy, what matter? I shall improve my English," he explains.

Valerian is typical of the student class, all ideal and aspiration. He has gathered the heat of the epoch, and has concentrated it upon his philosophy. He is saturated with the French Revolution. Does he mention Danton, for example, it is with intentness of loyalty for the great Mountain speaker, which makes one almost think that the year is 1792, and that the place is sans-culottic France; "debout contre les tyrans!" He sings fiercely with his comrades, to the tune of the _Marseillaise_, the Russian revolutionary anthem, ending it with a swirl. "For the palace is foe to our homes!" America he considers one of the free nations, but he has reserves. Though he is not at one with our political system, yet he thinks that all learned about it is a great gain.

"Your land is free politically," he specifies, "but it is not yet emancipated from capital,--it is not free socially. You have an industrial feudalism and a proletariat. So will it not be when we have won our revolution."

Many are his anecdotes of the uprising of 1905, whose tragic drama will never be fully pictured and whose history is to be gleaned only from the mouths of cautious witnesses.

[Illustration: THE ORGANIZERS OF THE CHITA REPUBLIC]

"We rose at Irkutsk, many of us, students and workmen, but General Müller had a strong garrison of troops here. We tried them, but they would not come over. They shot down our men and dispersed all the meetings, and now he is Governor in the Baltic Provinces. They say that when he was drunk, he would shoot accused men in his own railway carriage; "the butcher!" we of the Cause call him. At Tomsk and Krasnoyarsk the city was held for weeks by our party. The railway men would not run troop-trains and the Government was paralyzed. Chita was held by a Revolutionary Committee of Safety. We manned the entrances with artillery. We took turns watching, and ran the whole city, not touching the money in the Treasury. But we were few, and word came that the insurrection was everywhere broken. Müller was marching from Irkutsk, and Rennenkamp came back with the troops from Manchuria. He promised moderate terms to all but the leaders. The townspeople were afraid, and rose against our men. Many were taken. Many fled away and got to Japan and America. Some were shot and some were sent to the Yakutsk. So it was crushed, and our great chance was gone."

"Will it come again?"

"_Ni snaia!_ The workmen are ready. The intellectuals are ready. The peasants back in Russia cry for land. Perhaps they too will be ripe next time, and the soldiers will be with us. In any case Siberia has seen the red flag float over the Chita Republic."

Many-faceted is the life in a Siberian city. In numerous ways it seems feverish and abnormal, for it represents the young blood of a capable race struggling upward, and knowing that in much its battle is desperate. The towns have hardly yet got settled methods;

they are outgrown villages where men of all stamps, who have become enriched in the new land, come for the pleasures or the benefit of a less monotonous existence. The traditions of peasant origins survive in the conditions and general civic neglect.

Irkutsk, once its novelties have become familiar, has lost its charm. That it is provincial is no discredit, but its amusements are of the grosser order, unredeemed by wit. Every evening the tawdry dining-room at the hotel echoes the songs and noise of the revelers. The same circle attends the theatres. The students discuss hotly the rights of man and the Valhalla prepared for all martyrs, and calm simple wholesome life seems to be reserved for the workaday world which moves on its slow toilsome upward way in silence.

There is, however, to-night an unwonted stir at the Hôtel Métropole. The corridors are thronged. A Russian friend points out the notables. The blue-uniformed official yonder with the gray mustache and the row of glittering orders on his breast is the Governor-General. Half a dozen members of the local bar, in frock-coats, pass through. In the dining-room a young lieutenant, dashingly clad in long maroon coat with the row of silver-topped cartouches and the clattering sabre of the Emperor's Cossack Guard, is being deferentially entertained by officers of the garrison. Three officials are taking champagne with two beautifully gowned women, Parisiennes even to their long pendant earrings. The hotel-pages in fresh red blouses and high boots pass here and there with messages. The waiters, with intensified deference, glide among the crowd in its many-colored uniforms and glittering war-medals.

"Who has arrived?" we ask, surveying the scene.

"A member of the Imperial Cabinet."

The announcement of his name has a personal interest and memories of earlier stays in Russia.

The Minister's life has been a romance indeed. Disagreeing with his family through liberal ideas, he went in 1862 to Birkenhead as a locomotive engineer, to the United States, to Argentine, and returning to Russia worked up from a very small government position to be chief of all the Russian roads, railways, and telegraphs, and Minister of Ways and Communications in the Czar's Cabinet. His brain threw the line of rails over half a continent. On the outbreak of the Japanese War he was called from his retirement to the colossal task of bringing to the front across the width of Asia half a million men, their artillery and arms, their food, their transport, all on the one line of rails. He has served under three Emperors and is life-member of the Senate.

You send a card in through one of the attachés. In a few minutes there is delivered to you the Prince's card, across which is written: "At noon."

At the hour appointed you mount to the apartment overlooking the Bolshoiskaia. Guards at salute, staff in brilliant uniforms, secretaries and callers in full dress,--the antechambers are full. You pass through to the furthermost room.

In a nest of books and maps, with blue-prints outspread on floor and chairs and sofas, is an elderly man in a plain frock-coat, without a ribbon or a button to hint his honors. He is vigorous, hearty, simple, almost unchanged from your earlier acquaintance, his keen flashing eyes hinting ever a reverse side to the great repose of his manner.

Personal questions occupy the first minutes, but presently we are into larger themes, and you begin to feel subtly the man's power. He has come on a special tour, to inspect, with his own practiced eyes, the projected double-tracking of the Siberian Railroad. Every brakeman and locomotive engineer, every traffic superintendent and division manager along the route knows he could step down from his private car and handle the levers and give them directions. His mind is a very vortex of ideas, and his range of conversation reflects world-wide interests. The talk gets to the American political situation and the race-problem. Later it shifts to the Japanese War, and he tells of some of his experiences getting the troops into Manchuria. A mention of the overland road to China awakens reminiscences.

"It was long before the railroad that I went over that route first," he says. He tells of his months-long horseback ride beyond Baikal before the railroad went through, inspecting the trade-route and the prospects of the country. By and by the conversation has got to the special problems of the Slav. With the straightforward frankness of a great nature which wishes the best for his country, he tells of the Russian aspirations from the standpoint of those who are facing the problems of the nation in their fact and practice.

"I too," he says, "was once for changing much in a little time, and worked to free the serfs and to start the elective Semstvos throughout the Empire. Alas! so much that they want is possible to no government! One cannot by enactment abolish want or bring all men to a _niveau_. We are trying to give every man the chance to rise, unchecked by any administrative barrier. But one sees

as he lives longer that all which one wishes cannot come at a _coup_. Great changes, great improvements, I have witnessed, but they have not come by violence. We must keep order, and hand on to our sons an undivided Empire of the Russias."

You leave this patient builder of the new order alone amid his maps and studies in the idle Sunday city. As you descend the steps, a black-capped student passes the door. He is humming the forbidden _Marseillaise_.

IV

SLEDGING THROUGH TRANSBAIKALIA

The sledge-route that leads to the Chinese frontier goes southward from Verhneudinsk across the territory of Transbaikalia. In old days one reached its starting-point by traversing the frozen Lake Baikal in sleighs, muffled in furs against the sweep of the terrible winds, with plunging ponies at full gallop.

Now, after mighty effort and at monumental cost, the line of the great railroad has been driven through the last obstacles that blocked an open way, and trains carry the traveler through the deep cuts and tunnels that pierce the barrier crags around the Holy Sea.

It is not the express that one takes at the Irkutsk station to reach the ancient fort, but the daily post-train, the servant of local traffic. Luggage-cumbered passengers crowd into the cars wherever there is a place. A few, and these mostly officials, establish themselves in the blue-painted first class. Many press into the yellow second class--merchants, lesser chinovniks, tradesmen, popes, and children on their way to the city schools. Swarms pour into the green wooden-benched third, where the thronging tousle-headed emigrants patiently huddle closer to give room to newcomers. Next to the engine, with its big smokestack, is the mail-wagon, on whose sides are painted crossed post-horns and the picture of a sealed letter. Behind this, with a sentry on guard, is the baggage-car. The sinister compartment of drawn shutters and barred windows is for the prisoners. In this princes or artel-workers, their identity unsuspected, can be run across a continent to their unknown places of exile.

The post-train starts from Irkutsk occasionally on time. In general, along the local line the time-table is about as reliable a guide as the calendars sold to the mujiks, with weather prophecies for each day of the year. Fifteen miles an hour is mean speed. Stops may be for minutes or for hours. One settles down therefore in the attitude sacred to a yachting cruise,--foie gras and bridge, if it is calm; double reefs and pilot-bread if it blows up. The high heavens alone know when we are to get in, and nobody cares. It is not unpleasant withal to sprawl over a great broad couch, and as the train crawls forward watch the white highlands slowly unroll, the towering cliffs and peaks with spear-like pines driving up through the snow, and the icy lake below.

For meals, one dashes out during the station-stops, and before the third bell gives warning of the start, devours meat-filled _piroushkies_ and swallows lemon-tinctured tea at the long buffet-tables decked with hollow squares of wine-bottles, and beer from the seven breweries of Irkutsk. If one has a teapot he can get boiling water from the government-furnished samovar, and milk from the peasant-women who stand in booths hard-by. He can add salt fish and hot fowl, together with rye-bread and butter, and then consume his rations at leisure in the compartment. At night the seats are let down, and one sleeps in fitful naps among the hills of baggage. When morning comes, an hour-long procession forms to take turns at the wash-bowl with its trickle valve, in a towelless, soapless, and cindered lavatory.

We leave Irkutsk at ten in the morning, and reach Verhneudinsk at seven next day, covering in twenty-one hours the 446 versts. Here is the last of the railroad. With troika, sledge, and tarantass, by highway and byway, over frozen rivers and camel-tracked trails, we must now follow the old road into the heart of Asia.

The post-station that serves as point of departure for the sledge journey lies some distance away, at the edge of the town. An _isvoschik_, after due bargaining, proceeds to transfer thither us and our dunnage-bags.

As we ride through the town, just waking for the day, the streets, the lamps, the telegraph-wires, the comfortable houses,--each and every symbol of civilization takes on a new significance now that it is to be left behind. On the parade-grounds the recruits are at the morning drill, shouting lustily in unison, "_Ras, dva, tre!_" to keep the step. We pass the barracks, the shops with their brightly illustrated signs, and ride under the wooden yellow-painted Alexander Arch.

[Illustration: BAIKAL STATION]

[Illustration: THE HIGHLANDS OF TRANSBAIKALIA]

Soon we reach a street of low log houses, and a lofty boarded enclosure is ahead. At its gateway is swinging a black signboard, painted with post-horn and the Czar's double-headed eagle. "_Postava Stancie_," is inscribed over the lintel. Between the black and white-striped gate-posts we swing into the courtyard. To the left stretches a low log house. To the right, along the wall, are ranked sledges. In front are the stalls. Grooms, whip in hand, stand around in the courtyard, muffled against the cold.

"Is the _gaspadine_ going on?" one of them asks.

On the reply, "Yes, at once," he scurries off to start harnessing, and you shoulder open the low felted door of the post-house and enter the big waiting-room.

"Three horses?" asks the young black-mustached agent within.

"Yes, a troika sledge."

He turns to the book of registry attached to the rough table by a long cord fastened with a big red seal, and begins to write.

"The name?" he asks. It goes down.

"The destination?"

"The Chinese frontier at Kiahta."

"Your first relay-station is Nijniouboukounskaia, twenty-seven versts."

The fare is set out in a printed placard posted up on the wall; as is the price of a samovar, fifteen kopecks, and all the other items that the traveler may require.

The agent hands you the slip: "One rouble, eighty-two kopecks, for two persons, the _gaspadine_ and his courier"; something under three cents a passenger-mile.

As you wait for the harnessing of the post-sledge, the courier overlooks anew the bags and counts out again the parcels. As light as possible must be the impedimenta. Now is the last chance for change.

The big station-clock ticks on. The agent moves about in the warm dusky silence of the house. The courier straps tighter the dunnage-bag.

"Look that your furs are snugly fastened," he says.

There is trample of footsteps by the door. A fur-clad, ruddy-faced driver stumbles in, makes the sign of the cross before the ikon on the further wall, and beckons to you.

"Ready!" he says.

Three shaggy ponies stand hitched to a wooden sledge, not high like those of city _isvoschiks_, but low and shaped like a wide bath-tub. The bottom is cushioned with hay and you are to sit some six inches above the runners. The bells hanging from the big arched _duga_ over the centre horse jingle as he frets. The side horses, that will run loose between rope-traces, look around at the _yamshik_ who stands by. He holds in his mittened hands four reins of leather, twisted into ropes--two for the centre trotter, one each, on the outside, for the gallopers.

You climb into the nest of rugs and furs superimposed upon your baggage! The _yamshik_ leaps to the precarious perch that serves as his seat. The whip falls, and with a bound the horses are off. Always one starts at top speed, however bad the way. Always one finishes at a gallop, however jaded the horses. It is the rule of the Russian road.

With bells jingling, the driver shouting to clear the way, and a white cloud rising behind, the sledge skims out between the log houses which flank the straggling street. Dogs bark and the idle passers-by stare. Fur-covered pigs scramble up with a squeal, and scurry from their resting-places in the road. Girls, with shako-capped heads, peer through the windows. Little chubby boys, in big brown felt boots, cheer.

Soon the uttermost houses of the town are left, and emerging we plunge into the country road through open fields, dazzlingly, blindingly white. The trotter's legs seem to move too fast, as if seen in a cinematograph. The gallopers, free of all weight and held

only by the two traces which fasten them, outrigger fashion, swing on like wild ponies of the steppe. Crude and massive as the sleigh may look, its burden is almost nothing on the hard compacted snow. The horses in the rush through the bracing air seem to be the incarnation of the wind. A rut in the glistening road does not produce a disjointing shock, for, as a huntsman's bullet glances from the skull of a wild boar, so the sleigh glides into the air and swiftly down again at a long low angle. It is a fact of "flying."

The cold is intense. After an hour of riding you have learned a certain lesson which adds to your experience. Whether the traveler shall make this winter journey equipped with full camp-kit, portable stove, folding-forks, thermos bottles, and shell-reloading tools, or Tatar fashion, with a rifle and a haunch of mutton, is important but not vital. Let him make sure, however, that the huge all-enveloping sheepskin overcoat is at hand to supplement the coats beneath, and that a shaggy sleeping-rug is provided in addition to the blankets. One obstinate newcomer started with the insistence that a mink-lined Amerikanski overcoat, with two heavy rugs as lap-robes, would be ample. After an hour on the road, he turned into a peasant's hut to thaw out upon boiling tea, while the driver went back to the town to buy the hairiest robe and coat obtainable. These were thenceforth worn on top of the initial outfit. Siberia for a midwinter sledging journey exacts this tribute of respect.

For versts the winter road follows down along the river between towering pinnacled rocks, where in summer eagles nest. The cliffs are vividly spotted with orange and green lichens; below they are fretted with the scourings of ice brought down in the spring freshets. All along beside the road are the familiar pine-saplings planted in mounds by the villagers to guide the way. In the vast monotony and drifting snows travelers would be lost but for these landmarks. Along the fertile river valleys hamlets are thick. A cluster of houses is met every six to ten versts. Presently the road leaves the river and bends to the left, cutting across fields. When it quits the bank, it climbs sharply a five-foot ascent. The driver does not even slacken speed. At the turn he swings the sure-footed ponies suddenly, and takes the slope, letting the outrigger bring up against a stiff clump of bushes. There is a crash, the sleigh has caromed off at right angles, nothing has befallen, and we are on again.

Verst after verst of plateau goes by, with rounded rolling hills of dimpled snow, treeless, houseless, a barren waste. Then comes a crest so steep that the horses can only toil up it at a walk, and the passengers must climb beside them. The forest closes in as the height is mounted,--white leafless birches and dark green pines. The light snow is seamed with rabbit-runs, and here and there are the far-spaced tracks of deer or wild goats.

A mound of stones and a small pole with a Buddhist prayer-flag--for here is the ancient home of the Buriats--mark the top of the ascent. There is a moment's halt while you climb in and the driver tightens the saddle of the centre horse; then down the giddy descent we sweep, in full gallop once more. The pines flash past, and you hold your breath in fear of the smash that must come should a horse fall, should a trace break, should a side rut swing the sledge over. One is, however, so close to the ground that an overturn is usually harmless, save to the clothes and the nervous system, both of which are at a discount in Siberian sledging. Then too the outrigger arrangement is such that the craft turns a quarter of the way over and slides on the supplementary runner until it rights.

The cold is intense. One wipes away the snow from his fur collar, and the dampness on the handkerchief has caused it to become frozen stiff. It is a crackling parchment that goes back into the pocket. Eyeglasses are unwearable, for the rising vapor from one's breath is caught and frozen on them in an opaque film. Fingers exposed but a moment become numb and useless, and uncovering the hand is an agony. Gradually as you ride, through the great felt boots, the triple flannels, the camel's-hair stockings, the fur-lined gloves, the coats and rugs, the cold begins to bite. You have become fatigued and depressed of a sudden. The driver points to your cheek, where the marble whiteness is eating into the flesh, and bids you rub it with snow. An involuntary shudder grips and shakes you relentlessly from head to foot.

It is time to stop. If you try to go on beyond the next station you will, if the gods are lenient and you do not freeze, get out nerveless and trembling, not for hours to rally strength and energy. The chill will cling, however hot the post-house oven. Even now you are weak, beaten down, querulous, in a sudden feeble old age. The shudder means that the human animal is near his endurance limit.

On an urgent call, with special preparations, you may travel for a hundred hours, night and day, without halt save for change of relays. Physically, it is possible to fight cold for a time. You can run along in all your furs beside the horses, you can beat your arms together, and rub nose and cheeks to keep the blood in motion. You can drink copious glasses of scalding tea in the post-houses, and live by stimulants on the road. Through ceaseless vigilance and resolution you can keep from freezing, even while intense fatigue creeps on and vitality is going. But the persistent awful shudder is Nature's red lantern. Run past it if you must,--it is at your peril.

Dark against the snows, now a low-lying village comes into sight,--Nijniouboukounskaia,--and among its first log houses is one bearing the post-horn signboard. A cry rouses the jaded horses to a gallop, and covered with snow, the sledge sweeps into the yard. Steaming and frosted white, the animals stand with lowered heads. Stablemen run to unharness them. Stiff with cold and muffled like a mummy, you clamber out, and on unsteady legs mount the steps to the felted door of the posting-inn. In the big bare room, beside the warm oven, robes and overcoats can be thrown off. A red-capped girl loads the samovar with glowing brands from the fire, and sets it humming for tea. Brown bread is produced and eggs, and a great bowl of warm milk. With these, and the contents of your bag of provisions, can be eked out a welcome _obeid_.

For the night's rest one need not seek a bed. There is never a spring to ease the bones from Verhneudinsk to Kiahta. There was discovered just once on the journey--at Arbouzarskie--an iron skeleton, bearing to a spring bed about the relation that the three-toed Pleistocene prairie trotter holds to a modern horse. The post-keeper had carefully hewn with his axe five pine planks to cover the gaunt limbs of it. The voyageur slept on the soft side of these timbers. Bed and board are synonyms in Siberia.

For a couch there is to-night the narrow wooden law-provided bench, or--a less precarious perch, and equally resilient--the sanded floor. For bedding, one has one's own blankets and coats. What if the shoulder slept on numbs with one's weight, or the corner of the soap-box in the traveling-bag, serving as a pillow, dents the tired head! One draws off felt boots and some of the outer layers of clothes, rolls the sheepskin about one, covers the head with a blanket, and sleeps like the forest bears in their winter dens.

Just before daybreak is the best time to start, so that one can cover the most road possible while the sun is up. At ten or eleven, an hour's stop for lunch is advisable, and then on again until sundown. It is better not to travel after nightfall, as the cold is so much more intense. We dedicate the evening to hot tea, and then turn to the blankets and the bench.

The stretch between Verhneudinsk and Troitzkosavsk, officially rated at two hundred and eighteen versts, is really somewhat longer. A run of average record took from 4:20 P.M. Tuesday to 11:30 A.M. Thursday--forty-three hours and ten minutes. This included all relaying, seven hours a night for sleeping, dinner and breakfast halts, two accidents (an overturning and a broken runner), and one calamity--a Siberian who snored. The actual driving-time, over a road for the most part hilly, was twenty-two hours, five minutes, or just about ten versts per hour.

Horses stand always ready, with special men at hand to harness. Drivers swing on their shaggy greatcoats, and with almost no loss of time one is out of the shadowed courtyard and on the road again in the dazzling whiteness of the winter day.

In traveling "post," however, with relayed sleighs and big empty guest-rooms, one does not become acquainted with the life along the way. One has only hurried glimpses of slant-eyed Buriat tribesmen, of galloping Cossacks, trudging peasants, post-agents, girls who carry in samovars and silently steal out, rosy-cheeked boys on the streets, and women at the house-windows. To know the people and see their daily life one must get away from the beaten highroad, strike out from the government-regulated inns, and blaze one's own path into the interior.

First, you get a low passenger-sledge, long enough to admit of stretching out, and without too many projecting nails on the inside; then, three good ponies of the hardy Cossack breed, that are never curried or taken into a stable through the bitterest winter. The best animals procurable are none too good for climbing the passes away from the river-courses. The whole outfit can be bought for three hundred roubles in any of the interior towns.

For drivers, there is a class of _yamshik_ teamsters, who spend their lives guiding the sledge-caravans which carry the local traffic. One of these men, Ivan Kurbski, can guide you through a whole province, and lodge you every evening with some hospitable friend or recommended host. Whether he has himself been over all the changing by-paths in the wilderness of the Zabaikalskaia Oblast, or whether he mentally photographs the directions of his friends regarding each village, is an unsolved mystery.

[Illustration: SLEDGING SOUTHWARDS]

When the day's journey is done, Ivan will drive slowly down the crooked street of the village he has settled upon for the night's repose, looking keenly for landmarks visible only to him in this country, where every village and every house is mate to all the rest. Sometimes he will ask a question of one of the innumerable urchins. But generally he seems of himself to hit upon the desired domicile. Day after day he will take you the sixty versts, lead you to the village stores to replenish the supply of candles or sugar, bring you surely to food and shelter at night, and take off all the burden of care for the outcome of each day's journey.

If for the third member of your personal suite you can get an old-time servant to keep the guns clean, build the camp-fires when midday tea is to be taken out of doors, bring in the baggage and rally the best resources of each halting-place, you are doubly lucky. You will be sedulously tended, and be treated partly as a prince, partly as a helpless baby.

Of this order is Jacov Titoff. Not the smallest personal service that he can render will you be permitted to do for yourself. The telling of unpleasant truths will be carefully avoided, however certain the ultimate revelation. Though honest beyond question, he pays you the naïve compliment of relying upon your generosity in all the little matters that concern provisions and petty luxuries. He will open the package which he is carrying back from the _torgovlia_ to extract matches and cigarettes for his own delectation, and will rifle unstintingly the reserve of canned _sardinki_. He cheerfully freezes himself waiting for deer, and stumbles up miles of snowy mountain in the beats. He is always in good humor, and without complaint for whatever comes. He is ready anywhere, at any time, to sleep or drink vodka.

Thus outfitted and manned, take your place, muffled in furs, and seated on the felt sleeping-blankets. Guns are at your side, the bag of provisions is in front, your own little ponies paw the snow. They start off now, trotting and galloping beneath the _duga_. The air is frosty, clear, and thrilling as wine; the snow is feathery and uncrusted, as when it fell months back; bells are jingling, and the driver is crying his alternate endearments and curses upon the shaggy ponies. Down the long rock-flanked river valleys, amid birch and pine forests, you will skim, by unwonted paths, through out-of-the-world villages, to see in their own homes the red-bloused peasants, the women spinning at the wheel, the peddlers and priests, the traveling Mohammedan doctors, the rough Buriats, miners and merchants, along the white way.

The smooth main road is left now for newly broken sledge-trails across fields and over snow-covered marshland. Every available river is utilized as a highway, for along its winding length the path, smooth and level, is marked like a boulevard by the evergreen saplings planted by villagers to guide the winter traveler. One can pierce the districts flanking the Chickoya's gorges, reachable at other seasons only by breakneck climbs. And one can see the real Siberia.

On this first night of his incumbency, Ivan Kurbski lodges us with friends. He leaves us for a moment while he enters the yard by the wicket-gate to make due announcement, and the ponies hang their tired frost-covered heads. Your own bows under an equal fatigue. But the wait is very brief. Soon the big double gates of the log-stockaded courtyard open. The horses of their own accord turn in, and swing up to the steps of the house. You are handed out like an invalid grand duke, and are welcomed at the threshold, with a hard hand-shake, by a red-bloused peasant who ushers you up the steps, across the low-eaved portico, and through the square felt-padded door into the big living-room.

As we all enter, Ivan and Jacov, caps in hand, bow and make the sign of the cross toward the grouped ikons high up in the corner opposite the door. The saints have guarded you on the way--are not thanks the devoir? Then you, as head of the party, must salute, with a "_Zdravstvouitie_," your host, the old _Hazan_ father of the peasant who, wearing a gray blouse sprayed with vivid flowers at breast and wrists, sits on a bench beside the window. Now you may sit down beside the massive table on the other bench, which is built along the whole length of the log walls, and survey the curious world into which you have fallen.

A woman of middle age, clad in bright red, is busy with a long hoe-like instrument pushing pots into a great square oven six feet high, ten feet to a side, and spotlessly whitewashed. To her right, in the room beside the oven, is a girl of fifteen or sixteen, rolling brown rye-dough on a little table, in perilous proximity to a trap-door leading into some dark nether region. An old bent woman gravitates between the two. Glancing up, one meets the wondering eyes of three sleepy blinking urchins, who peer down in solemn interest from a big cushion-covered shelf, two feet beneath the ceiling. Looking about to locate the muffled sound of crows and clucks, one discovers, beneath the oven, a corral of chickens, pecking with perky bills at the whitewash for lime. On the floor is sitting a little girl crooning some endless refrain to a baby in a sapling-swung cradle.

"The _gaspadine_ will take _chai_?" asks the patriarch. From the woman's room beside the oven the girl brings a samovar. She sets it on the floor, beside an earthenware jar standing near the door, and dips out the water to fill it. Then with tongs she takes a long red ember from a niche cut in the side of the oven, and drops it down the samovar funnel. Round loaves of frozen rye-bread are brought out and set to thaw. A plate of eggs is produced from the cellar. One rolls off as the girl passes, and falls to the floor. Instinctively you start. Not so the others. The egg has dropped like a stone and rolled away. But it is quietly picked up and put to boil with the rest. It is frozen so solidly that there is not even a crack on the shell.

Jacov meanwhile is making earnest inquiry of the "old one."

“How are your cows, Dimitri Ivan’ich? Your horses, are they well? And your sheep? All well? And have you had good crops? Is there still plenty of pasture-land in this village? _Good!_ GOOD!--and how is your wife?”

Poor withered wife; she is bustling around looking after the children, and trying to help her daughter-in-law. Not so the “old one,” the ancient man of the family to whom these courteous questions are addressed. The patriarch stopped his labors at fifty, and sits slumbering away his second prospective half-century in honored idleness. “Everybody works but father!”

The samovar is humming now, and the table is decked with a homespun-linen cloth ready for the _obeid_. The first formality, as dinner is about to begin, must be observed. The various members of the family turn, one after another, toward the ikons, reverently crossing themselves. Then the host produces a bottle of a colorless liquid, shakes it up and down, and brings the bottom sharply against his palm. The cork shoots out, and he pours into a little glass a drink of the national beverage, vodka, which one is supposed to swallow at a gulp.

Every time a guest enters, a bottle of vodka is brought out, costing 49¼ kopecks, half the average day-laborer’s pay in this district. On feast-days the visitors go from house to house drinking,--and these _prasdniks_ number some fifty-two days in the Russian year. Every business deal is baptized with vodka. Every family festival, the return of a son from the army, the marriage of a daughter,--all are vodka-soaked. As one passes through villages on a saint’s day, he may meet a dozen reeling figures and hear the maudlin songs from the courtyards where the men have gathered. The part played by vodka in the people’s life is appalling.

In the house now, all, beginning with the “old one,” partake of this stimulant, solemnly gulping down their fiery potions. Then the family sits down in due rank and order, the “old one” in the cosiest corner, with the samovar convenient to his hand. You, as the guest, are beside him on the bench that lines the wall, then comes Jacov, next the son, then Ivan Kurbski the _yamshik_, and on stools along the inner side of the table, the grandmother and assorted infants. The mother alternates between the table and the oven.

The samovar is tapped for tea as the first course of the evening. For all who come, tea is the obligatory offering, in a cup if the visitor be familiar, but for special honor in a glass with a ragged lump of sugar hammered from a big cone-shaped loaf. This one nibbles as he drinks, for sugar is a luxury, not to be used extravagantly. The brown rye-bread, which has been thawed at the gaping oven-door, is next brought out, and raw blubber-like fat pork, in little squares, eaten as butter, and boiled potatoes, and the boiled eggs, curdled from the freezing.

At Little Christmas, the _prasdnik_ day which comes in early January, _pelmenis_, or dumplings, egg-patties (grease-cooked), and meat will be served, with cranberries and white bread. In Butter-Week everybody gorges on buttered _blinnies_, or pancakes, garnished with sour cream. Even a substance showing rudimentary traces of a common ancestry with cake may be produced.

As the shadows of the northern evening close down, a piece of candle is lighted to-night in our honor. Generally the burning brands for the samovar, propped in a niche cut at the height of a man’s shoulder in the outer edge of the oven, throw the only light. Presently the candle is used up and the brands give a fitful flame, leaving the corners black as Erebus.

From the baby’s cradle comes now a plaintive cry, and one of the little girls goes over to dandle it. Up and down, to and fro, for hours together she works, singing her monotonous lullaby. The children, who have been lifted down from their eyrie above the oven, play on the sanded floor. The men remain oblivious and smoke their pipes, letting fall an occasional word, which comes forth muffled from their great beards.

Ox-like, all sit for a while, sipping occasional cups of tea. Then the woman and the girl go out and get wood, remove the pots from inside the oven, and build up a roaring fire. The children are rolled up for sleep in their little blankets on the floor. The men reach for their furs and felts. They go to the left of the oven, the women to the right, and the children are between, making a long row in front of the fire. Soon all are sunk in heavy sleep. The little girl alone sits up to rock the baby. As you doze off in the genial warmth of the newly-stoked oven she is still crooning her lullaby in the dim fitful light of the firebrands.

Through the long night all lie like logs. Toward morning, as the oven’s heat dies down and the bitter cold creeps in, sleep becomes uneasy. One stirs and then another. Finally the woman rises and wakes the girl, and they go out into the cold for wood and water. Presently the men bestir themselves, get up, and wait for their tea. The rising sun of another day casts its rays through the windows.

As the sleepers one by one arise and stretch, their blankets are folded by the watchful woman of the house, and thrust up on the children's shelf. Some of the men go across the room and let the water from the little brass can in the corner trickle over their hands. Some do not do even this.

For the outlander of washing proclivities, peculiar problems are offered by a country of no wash-bowls, no soap, only occasional towels, and the tea samovar as the only source of hot water, a copious draft on which not only postpones breakfast but compels some of the women of the family to go out and chop ice for a new supply. Necessity evolves the tea-tumbler toilet method as our solution. You borrow one of the precious tea-glasses from the old woman, fill it to overflowing with warm water from the samovar, and prop it up on the window-sill. The top inch of water is absorbed into a sponge which is put aside for future use. Into the remaining two and a half inches a soaped handkerchief is dipped, with which one washes one's face, touching tenderly the spots recently frozen. The reserved sponge will do to rinse off the detritus of this first operation. Two and a quarter inches of water are left, of which half an inch may be poured over the tooth-brush. With an inch and three quarters left, one has ample to lather for a shave, as well as to wet the nail-brush which is to scrub one's hands that will be rinsed with the sponge. Half an inch remains finally to clean the brushes and razors. "There you are!" With two glasses one may have a bath.

When the breakfast of rye-bread and tea is ended, the men go out to their various winter tasks, of which the most serious is felling trees in the forests, cutting them up, and getting home the wood. The women keep stolidly at their cooking, cleaning, child-tending, and turn to the spinning-wheel and hand-loom when other work does not press.

In the weeks that follow, each night brings us to a different home, but never to a changed environment or atmosphere. This type of life is found, not only among the Trans-Baikal peasantry, but throughout all Siberia. The log houses down the long straggly village streets look out upon the same wooden-walled courtyards,--the women peering from their little windows as the sleighs jingle past. The same ikons with burning lamps look down as you enter; the same whitewashed oven and shelf and cradle are there as you push open the felted door. The women of each district wear the same traditional costume. The bearded host produces the same vodka. One of the most impressive sights, when one drives out before dawn into the frosty air, is to see at almost the same moment from every chimney the black smoke roll upwards, then dwindle to a thin gray streak. Each woman has risen and heaped green wood into the cooking-oven. It is as if one will actuated simultaneously all the people.

At places the master of the house has a trade, shoemaking or saddlery, and the big living-room is littered with pieces of leather and waxed cord as he stitches. Sometimes there are hunters in the family, and ancient flintlock muskets rest on the antlered trophies. The men gather together occasionally to drive deer. But in general, as the winter is the men's idle time, a little wood is cut, the cattle are seen to, and for the rest, talk, tea, and tobacco, until it is time to eat and sleep once more. The women on the other hand seem to be always occupied, but they are not discontented.

[Illustration: PEASANT VILLAGE STOREKEEPER SIBERIAN TYPES]

The customs and institutions which bind together the household group are unique. In all families the _Hazan_ is supreme. To him first of all, strangers pay their respects. To him every member of the household comes for advice as to whom he or she shall marry, and which calf shall be sold. Howsoever hard of hearing he may be, there is related to him all the events of the neighborhood with infinite minuteness. He is the repository of all moneys earned by logging for a neighboring mine-owner, or for bringing out to the railroad the sledge-loads of rye. As head of the family he can summon a forty-year-old son from the merchant's counter in Krasnoyarsk, or his nephew from the fur-traffic in Irkutsk, and bid him return to his peasant hut. If a grandson wishes to go to Nerchinsk to seek his fortune, the "old one's" consent must be obtained before the youth receives his passport. It is all at the patriarch's sovereign pleasure.

We come one day upon a vexatious example of this ancestral authority. A report reaches us, by chance, of a hibernating bear's hole some fifty versts away, which one of the peasants has located. The host, noting our interest, asks:--

"Would the _gaspadine_ like to hunt him?"

There is no question on this score, so the peasant is quickly brought to the hut. Numerous friends crowd in with him, for one person's business is everybody's business in these primitive communities. For a liberal equivalent in roubles the man agrees to act as guide, and the start is to be made early next morning. All is arranged and he goes out with his body-guard to make the necessary preparations. By and by there is a stir. Our sledge-driver comes in with a long face. Then half a dozen peasants add themselves to the family quota in the hut. Soon more come, until the stifling room is as populous as a Mir Assembly. They are all

talking at once, and there is a great hubbub. At length one voice louder than the rest seems to call a decision for them all. They turn backward again, and with many gesticulations bustle through the felted doors into the snowy streets, and through the village to a house which they enter in a body as if with intent of sacking it. Instead they bring out and over to our hut a slight bearded old man, bent with the weight of many winters--the father of the peasant guide.

Humble but resolute, he faces the assembly.

“No, I cannot consent that he lead the _gaspadine_ to the Medvetch Dom.”

“But assure the ‘old one’ that his son will only point out the den and then go away.”

The “old one” answers:--

“The bear does not come to steal my pigs. Why should I get him shot? Besides, a bear chewed up three Buriats last year. It would be sad to be devoured even for the _gaspadine’s_ fifty roubles.”

The reward is doubled, and forty kopecks’ worth of vodka produced. Many advisers give aid, and one suggests that “the son may mount a tree one hundred _sagenes_ from the mansion of the bear!”

But still the father refuses. “No, I will not allow him to take out his horse and hunting-sledge.”

The son, whose half-dozen full-grown children are looking on, shakes his head dolefully. A big eagle-nosed peasant, of hunting proclivities, comes in.

“I will give my hunting-sleigh if he will go,” he calls.

But the shrill voice of the “old one” rings out again, “I do not consent. I do not consent. My son shall not go to the mansion of the bear.”

The guide shrugs his shoulders. We have hit the ledge of Russian authority. No one will budge. The old man has his way.

As is the management of the household, so is that of the village. While the _Hazan_ rules over the common property of the family (_izba_), the village elder (_Selski Starosta_) is guardian over the grouped households which make up the Mir. As the household goods belong to no one individual, but are common property, so the land farmed by the villagers is a joint possession whose title rests with the commune. The family is held for the debts and behavior of all of its individuals; and similarly, with certain limitations, the village community is answerable for the taxes and discipline of each of its members.

On a humble scale it is the spirit of socialism incarnate. Within the commune no capitalistic employers, no wage-taking worker-class, no castes exist, and no individuals are born with special privileges. No distinctions of rank or fortune lift some above their fellows. The manner of living is the same for all. Each head of a family has a right of vote, and elects by the freest, simplest means his own judges and village rulers. The land, the source of livelihood, is divided among the producers by their own unfettered suffrage.

The chief man of the community--he who drums out the voters to the Mir, lists those who do not work sufficiently on the pope’s field, and reports the toll of taxes to the Government--is simply an elderly peasant clothed with a little brief authority. There is no household in the average village which is looked up to as more genteel than the rest. No such distinctions as prevail in America will reveal that such a farmer’s family is musical and well-read, such another has traveled to Niagara Falls, such a third has blue-ribbon sheep. In Russian peasant circles all is equality, almost identity.

Here is presented the best example in the world to-day of an applied system based upon the communistic as opposed to the individualistic theory. It is therefore of more than local interest. Most apparent of all results is the economic stagnation which has accompanied the elimination of special rewards for special efforts. The man, more daring or more far-sighted than his fellows, who would take for himself the risk of a new enterprise, who would mortgage his house to buy a reaper, or would seek a farther market, is fettered by his plodding neighbors. His financial obligations, if he fail, fall on the others of a common family, whose members have a veto on his freedom of action. His own and his neighbor’s fields by the allotment are proportioned in extent to the old hand-labor standard. A machine has few to serve until the fields are readjusted to a new standard. While technically a man may buy or rent lands outside the commune and may introduce a new rotation of crops or agricultural tools, actually the inertia of the peasants bound to him by the brotherhood of the Mir weighs the adventurous one hopelessly to the earth. Who can persuade an

assembly of bearded conservatism-steeped “old ones” to buy for the Mir the costly new machines? Perhaps, with the visible demonstration of profits which private enterprise could make under an individual régime, the doubting elders might consent. But who is there to show them when every village checks back the swift to the lock-step of the clod?

Nor is it simply in material things that communism manifests its lotus-fruit in these country hamlets. Ignorance, unashamed, broods over them one and all. What a dead level is revealed by the fact that one peasant in a populous village on the Chickoya, our guide upon a shooting-trip, could not tell time by a watch, and had never seen such an invention.

Some instances are related where the more ambitious men of a Mir have clubbed together to bring in a teacher at their own expense. The Semieski, or “Old Believers,” big, red-bearded, obstinate men, settled in Urluck in the Zabaikal, who dissent from the sixteenth-century revisions of Bishop Nikon, will not send children to Slavonic schools and may have schools of their own. But these cases are rare. There is among the peasantry almost no education and comparatively little desire for it, yet how far this sentiment is from being a racial or national failing the crowds that come to the city universities bear ample witness. In one of the villages a teacher from Chita is established in the side room of a peasant’s house, wherein one night we sojourn. He has been appointed by the Commissioner of Schools of the Cossack Government. He is of a good Nerchinsk family and is brother to an elector of delegates to the second Duma. He is one of the “Intellectuals”--the student class which forms almost a caste by itself. A free-thinker, keenly interested in the rights of man, a Social Democrat by politics, he goes shooting on Sunday with some peasant cronies. He plays Russian airs on his _balilika_ and gets the peasant’s daughter to dance for the guest. He produces specimens of antimony and chalcopyrite, and discusses the geological probability of finding silver or platinum ores in these districts. Photographs of the amateur-kodak variety are along the walls, and on a table in the corner are a mandolin and a pile of books. We pick up a volume,--“L’Évolution de la Moralité,” by Charles Letourneau. The young owner, who consumes a prodigious number of Moscow cigarettes, tells of the indifference to education among the people.

“Here we have a school in a big village, with two other communities near by. There are easily five hundred households,--with how many children in each, you can see. Yet we have but thirty boys at school. What can we do?”

He is discouraged, this single “Intellectual” of Gotoi. Profoundly solicitous for the future, an idealist, boundless in hopes for the good of his race, he sees the younger generation submerged at the threshold of opportunity by the inertia of the old.

“‘What good will it do for him to read?’ ask the peasants, when I urge, ‘Send your boy to the school.’ What can I say? The boy comes from my class after two years, and goes out with the men. He has no money to buy books if he wants them. No newspapers come to the village, no printed matter whatever, save that on the pictures which they buy in the fairs. In a few years all I have taught is forgotten. The darkness is over these villages. One must lift them despite themselves.”

Beyond the range of the village communes, no people show a more eager zeal for knowledge and study. In the cities almost all of the younger generation can read and write. The school-boys, with their big black ear-covering caps, smart blue coats, brightened with rows of brass buttons, and knapsacks of books, are one’s regular morning sight. “Realistic” and “Materialistic” schools are established in many towns.

The apathy of the rural element is to be laid at the door of the system which hinders those within the confines of the communes from reaping the fruits of special sacrifice and effort. No one attempts to raise himself in the Mir, where the dead weight of those bound to him is so hopeless. If any boy, brighter than the rest, follow some lodestar, it must be to a city. The aspirant must bury ambition, or leave the drudging Mir with its toll of taxes and recruits. He will not study law before the wood-fire as did Lincoln in his log cabin.

The cloud of deadening communism over their lives utters itself in the words continuously on the peasants’ tongues. It is the northern equivalent for that buttress of despotism--“_mañana_.” The possibility of the Russian condition is “_nietchevo!_” If the red cock (_krasnai petuk_) has crowed and has left the forty householders with charred embers where stood their homes, “_nietchevo!_” They build it up of wood and straw, with the oven chimney passing through as before. Does a raging toothache torture, “It is the will of God,--_nietchevo_!” If the weary day’s climb sees a gameless evening, “_nietchevo!_” If the son is frozen in the troop-train, “_nietchevo!_” If the Little Father send to Yakutsk the other one who has gone to the city, “_nietchevo!_” Is the unrevised tax for a family of ten men pressing down upon three, “It has got to be borne,--_nietchevo!_” It is this bowing to fate as a thing begotten of the gods, when it is a force to be fought here on earth; the long-taught submission to evil, when evil is to be conquered, to limitation when opportunity is to be won,--it is this spirit which is holding rural Russia still in her Dark Ages.

The origin of the present village-system goes back to the time of serfage, when the overlord held his dependents herded together for easy ruling. That it extended to unfettered Siberia, where the rewards of individual effort were so obvious, cannot be laid entirely to old custom or government compulsion. Nor is it to be explained by the early necessity for protection against wild beasts or hostile natives. The same dangers threatened the pioneers of our own country. Perhaps the Russian spirit of gregariousness lies at the root of the fact that in the Czar's domains the peasant lives away from his fields to be near his neighbors, while our people live away from their neighbors to be near their fields. Whatever the cause, the outcome is that practically the whole rural population, even in the most thinly settled districts, is gathered into villages, and owns the lands in common.

The system makes enormously for homogeneity, welding, solidarity. The people are a "mass." Units are lost in unity. Nothing save Nature's imprint and law of individuality, that decree under which every created thing is some way different from every other, keeps the Russian peasant from quite losing his birthright. The commune, vodka, and resignation are the incubi of Siberia. In the towns and cities gather the energetic natures that have climbed out and above them. What these have done, their allied people--the peasants--can do. Beyond the horizon of the latter's narrow lives lies still the borderland of possibilities. One cannot doubt the vigor of the stock, nor the certainty of its rise. This quality of rugged worth is the basis of all the great advance that the pioneers and the city populations have made. It is only in the Mirs, frozen fast in their lethargy of communism, that resurrection seems such a far-off dream. The way is long for the peasants of Siberia--long and toilsome. But their vast patience is allied to as vast a courage, and both will lift them into the larger day.

The measure passed by the last Duma, decreeing the division of the Mir lands in severalty, and private ownership of property, will be one of the most momentous and far-reaching enactments ever legislated for a people. It should end for rural Russia the stagnation, and open an era of mighty endeavor and achievement.

There are many races here among the serenely tolerant Siberians, undiscriminated against and uncoerced. While one of the Orthodox may not abjure the state religion without severe punishment, those born to an alien faith are unmolested by official or proselyting pope. "God has given them their faith as he has given us ours," is the Russian rule.

This medley of races beneath the Russian banners gives to one's earliest contact the conception of a heterogeneous disorganized jumble of nations and peoples. But closer acquaintance impresses upon one the dominating and surviving qualities innate in the Slav, whose unalterable solidarity is beneath and behind the kaleidoscopic types of aboriginal tribes and exiled sectarians. By race-absorption, like that which has evolved Celts, Danes, Saxon, and Norsemen into English; British, Dutch, Swedes, Germans and Italians into Americans, the Slav is dissolving, transmuting to his own type and moulding to his own institutions the varied peoples.

Though the heterogeneous blood adds to the total of Siberian country life, it is the Slavic race that determines the permanent order of this great land. Primarily too it is the peasantry who shape its destiny. Their possibilities are the limit of Russia's ascent. Their condition is therefore of far deeper than sightseeing interest to the student. Unlike the picturesque peasantry of Holland, here they are the foundations of the state, forming not an insignificant minority but ninety per cent of the population.

Somewhat of a new spirit flickers here and there in Siberian hamlets. The peasant is superior to his Russian brother. The traditions of serfdom were broken by his severance from the old environment, and wider lands give him an abundance unknown save in a few favored parts of Europe. The political exiles have through the centuries added an upsurge of independence and personal self-consciousness, which is markedly higher than the Oriental humility of Occidental Russia.

The influence of the criminal, as distinct from the political convict, is felt primarily in the cities, such as Irkutsk and Vladivostok, to which the time-expired men drift. The convict element is always met with. It has been customary to billet a condemned, who was not wanted at home, upon some out-of-the-way village, giving him a passport for its confines alone. The victim might have been a Moscow professor or a locomotive engineer, but in the Mir he must farm the land given him. Naturally such seed as this planted in Siberian hamlets does not produce the traditional peasant faith in God and the Czar so faithfully preached by the popes.

Another influence making for upheaval is the returning recruit. We are in a peasant house when a _soldat_ comes back to the family from his service. If he has not brought any great burden of salary, he has accumulated tales enough of the outer world to hold in breathless excitement the circle of friends and relatives which gathers at once when the tinkling sleigh-bells and the barking have announced to the village his return.

Far down the street is heard the jingle of his sledge. It brings every girl to her peep-hole window, and every boy from his sawing to the courtyard door. At the gateway where the newcomer turns in, he is heralded by the commotion of the household guardians, wolf-like in appearance and nature. Everybody within the important house runs to the door. The village knows now which family is making local history. The arrival is accompanied already by two or three men who have recognized him as he descends. He tramps in with military firmness of tread, head erect. Before he greets the grandfather even, he makes the sign of the cross to the holy ikons, and, bowing down, touches his lips to the floor. Then comes the respectful kiss to the old man, next to the mother, while the younger brother, soon to go to service himself, stands awkwardly by, and the little children look half-dubiously at a form scarcely known after his four years of absence.

Then there is a scurrying of the grown and half-grown daughters to prepare _chai_ and to produce the _pelmenis_ and brown bread. The villagers drift in one by one, cross themselves, and speak their greetings, until the little house is packed, and as hot as the steam-room of a _banno_. The vodka-bottle is out and everybody has settled down for an indefinite stay. The soldier's tales of war and garrison duty and government and revolution hold the family and the audience breathless through the long evening. As you drop asleep, the hero is still reciting and gesticulating. The guests in departing will be careful not to stumble over you, so _nietchevo_.

In one of the houses where we put up, a shop adjoins the big living-room. It has dingy recesses from which hatchets and the commoner farm utensils can be produced, shelves of homespun cloth, and gaudy cottons for the men's blouses, and beads for the women's bonnets. Here, as in the country-stores of our own land, during the long idle winter days there is always a crowd and endless discussion of the village events,--the health of each other's cows, births, marriages, deaths, drafts into the army, taxes. Even in this remoteness something of the echo of great Russia's struggle is heard over the shopkeeper's tea-cups. We hum, unthinking, a bar of _Die Beide Grenadier_, in which a refrain of the _Marseillaise_ occurs.

A peasant looks quickly up. "It is not allowed, that song," he says.

"Why not?"

"That is the song of the strikers."

"But the _gaspadine_ is a foreigner. He may sing it."

"Yes," says the peasant, "he may sing it, but I may not. Would that I might!"

One meets quaint characters in this inland journeying--veteran soldiers of the Turkestan advance; "_sabbato_ sectarians," who keep Saturday holy rather than Sunday; austere "Old Believers," traveling peddlers, teamsters who have tramped beside their ponies over three provinces. One comes upon peripatetic Mussulman doctors, in snug-fitting black coats and small black skull-caps, who show their Arabic-worded road-maps and much-thumbed medical works bound in worn leather. Beside their plates at table the kindly hostess puts piles of leathery bread, unleavened, and made without lard in deference to their caste rules.

[Illustration: PEASANT TYPES]

A shop in one village is kept by a Chinaman, who, lettered like most of his race, seems a far shrewder and more intellectual person than the uneducated Russian peasants. He invites the stranger to drink tea that his special caravan brings, and presents Chinese candy with the courtesy of a grandee. When, in reciprocity, the traveler buys sugar for his _chai_, he receives it wrapped in paper covered with hieroglyphics and exhaling the faint unmistakable Chinese odor.

Going always southward, one begins to meet more and more frequently the villages of the Mongol-descended Buriats. "_Bratskie_" (brotherly people), the Russians call them, for despite the forbidding aspect that flat Mongolian features, high thin noses, yellow-brown skins, and big squat bodies give them, no more peaceful, harmless, and hospitable people exist. They are great and fearless hunters, unexcelled riders, and though still only on the threshold of civilization, are rapidly moving to better things.

All phases of the advance from the nomad to the agricultural stage may be studied among them. The pastoral Buriats, decorated like the Chinese with queues, ride around after their flocks. Their villages lie far away from the lines of convoys, unmarked on the Ministry map, which one is supposed to be following. Each family occupies a little windowless wooden hut, some fifteen feet in diameter. In front of it is planted a pole, carrying at the top a weather-faded pennant, the colors of which in Buriat heraldry indicate the tribe and name of the occupant. Behind the hut are stacks of hay and a wooden corral with sheep and horses. Beside it stands the summer tent, of felt, looking like a great inverted bowl. It is empty in winter, save for a shrine with grotesque pictured gods,

fronted by offerings.

In the homes of these least advanced Buriats we loiter no longer than we must. The wooden house which shelters them is hermetically sealed, and is crowded with people and animals. Fenced off in a corner of the first that receives us is a corral of thirteen lambs, which at uncertain moments begin to bleat suddenly in unison, producing, with startling effect, a prodigious volume of sound. When one has been roused from sleep half a dozen times a night by this chorus, he is strongly inspired to move on. The men are out during the day looking to their flocks. The women spend a good part of their time sewing furs or making felt. They are very unclean, and it is a decided relief to get out of their homes, to which the cold compels one to have recourse on a long journey. In spring, with great and understandable relief, these semi-nomads take to their felt tents and move where fancy and pasturage dictate.

One grade higher are those Buriats who have learned some rudimentary farming from the Orthodox. You will see the men threshing on a level floor beside the corral. They are dressed in long blue or magenta fur-lined cloaks and colored cone-shaped hats. Other Buriats are permanently resident in the Slavonic settlements, and send their rosy-faced children to school. They mix with the Russians, subject to almost no disabilities, and their better classes contract inter-racial marriages, which seem, to an outsider, at least, completely happy and successful.

It is no small thing, this which Russian rule has done for the Buriats. A people whom any other nation would spurn in racial ostracism, perhaps would eliminate, live side by side with the good-natured Slav in perfect accord, progressing in civilization and material well-being as high as the individual can aspire to and attain.

They are ruled by their own chiefs, whose sway is tempered by the benevolent supervision of the general government. They are represented in the Duma by men of their own selection. They freely worship the Buddhist Burhan in their lamasery near Cellinginsk, without pope to preach or missionary to proselyte. Their easy citizenship is unharassed by money taxes, and their only obligation is Cossack service in the army. But Cossack service to a Buriat is what a picnic is to a boy. Riding around on horseback, rationed by the Government, visiting a city with real tobacco and vodka sometimes attainable, sleeping on a straw-stuffed mattress with no tethered lambs to murder sleep, when they are used to a sheepskin on the dirt floor,--all this is luxury of blissful memory, during the years of the reserve. The net result is that the Buriats are entirely content. They are progressing all along the line, and are being made useful to the nation, not by unpayable taxation, but by the service which they are so especially fitted to render.

As one nears Chinese territory, by the lower waters of the Chickoya River, the villages of Slavic colonists who hold their land on tax-paying peasant tenure, have given place to the Buriat tribesmen and to the _stanitzas_ of the Cossack guard that occupy the pale of land flanking the frontier. Within this border-belt, every village _stanitza_ holds its quota of Cossacks. These soldiers are for the most part descendants of the levies from the Don region, transplanted to the Trans-Baikal by the Government's despotic hand in the eighteenth century, and since then forming an hereditary military caste. Many of them are bearded Slavs, indistinguishable, save for their accoutrements, from their more peaceful neighbors. Others are of a peculiar cast of countenance, due to the mixture with the Asiatic tribes in ancient times, when the hunted people fled to their ancestors' asylum, the territories beyond the Volga and on the Don. There is great variation in type among the imported Cossacks. Most are Orthodox, but a very large number are "Old Believers," or Semieski. In all the houses now hang the yellow cap and the uniform coat, which must be ever ready against the call of duty. Arms are in the corners of the rooms, and everything has a military look, in marked contrast to the peasant homes. Crude, highly-colored prints of Japanese defeats, which circulated broadcast in Russia during the war, share the attention usually devoted exclusively to holy ikons. Portraits of Generals Linevitch and Kuropatkin, and Admiral Alexiev, are tacked to the walls. In one house we saw hanging a prized silver watch, one of those distributed by General Rennenkamp among the soldiers of his command.

One of our Cossack hosts is an old man, Orthodox, and of Russian origin, but with some ancient Asiatic blood, for only a stringy beard grows on his kindly, wrinkled face. With reluctant pride he tells of his three sons away on service, leaving but himself and two daughters at home. With frank happiness he shows you his medals. Every soldier at the front received a round brass service-medal; his, however, a silver cross with St. George and the Dragon on it, is given for valor. He will not drink the vodka he offers you,--rheumatism. But in order that you may smoke some alleged tobacco that greatly interests him because he gathered it himself by the roadside, in Manchuria, he starts up his pipe despite the dust-induced coughs that it begets. He is a kindly, loquacious old man.

Another Cossack, privileged to the broad yellow top on his cap and the yellow stripe on his trousers, is, for the time, our guide and gun-carrier. His flat strongly-mustached face is open and ingenuous. He tells of his _sotnia_ in Manchuria.

“I was with Mitschenko at the front during the war, in his great raid,” he says. “Ten of our _sotnia_ of a hundred were killed, forty wounded. We got behind the Japanese and burned four hundred of their wagons. We had two hundred rounds of cartridges, and more when we wanted them. But food often not, and meat sometimes not for two months. We had thirty Buriats in our hundred, but the Verhneudinsk Polk were almost all Buriats.”

In one house where ikons, oven, bench, and stockade reveal the Slav peasant’s home, the mirrors are shrouded for their forty days’ veiling. It is a place of death. The owner was a full-blooded Buriat married to a Russian woman. In silent grief she plods through her mechanically-executed duties. Their son, in red blouse, is in prayer beside his father’s body. They have pressed us to remain. The advent of strangers seems to distract their thoughts a little. From outside comes a hail, and heavily there dismounts from his pony an old grizzled Buriat Cossack. He has ridden two hundred versts to pay this last respect to his friend.

His military training makes the Cossack a little less gentle than the average peasant. When off duty, hen-roosts near a garrison are in some danger. For the rest, he is naturally brave, generous, and will share the chicken he has just ridden forty versts to lift. He will give his pipe to be smoked, and will behave with a thoughtfulness and courtesy that is not found in finer circles. His children have the free unrepressed air which speaks of genial home kindliness and sympathy. His wife is far from being a mute drudge.

Assuredly this is not the Cossack of legendary fame, the “implacable knout” of the czars. It requires almost courage, in the face of the savage of literary tradition, to assert that the Cossack is other than a dehumanized monster of oppression. Why then did he cut down with utter ruthlessness the helplessly frozen grenadiers of the Grande Armée? Why will he massacre indiscriminately men, women, and children on his path from Tien-tsin to Peking? Why will he beat with his knotted whip the striking girl students of Kiev? Who shall tell? To a certain extent he is callous to suffering because of a defective imagination. He will ride his best horse to death if need be. Loving it, he will yet leave it out in weather forty below. He is cruel, often, because he has not the substituting gift needed to translate another’s suffering into terms of his own. He is valorous because, even so far as regards himself, he cannot think beyond the immediate privation into the future of imaged dread, so he goes fearlessly into unpondered peril. He offends the traditional ideas of humanity and civilization in killing people, because of his failure to recognize a wider radius of sympathy than circles his own tribe. But if the tribe circumscribes his idea, the nation circumscribes the sympathies of others who make tariffs to crush an extra-national industry and raise armies to destroy a foreign liberty. But if outside the Cossack’s recognized circle, you are to him beyond the pale, in his home, you are, _ipso facto_, a member of the tribe, a brother in whose defense he will gayly risk his life, and spend his substance.

The deeds that are recalled to the Cossack’s discredit often fall for judgment really to those who plan and issue the orders which loyalty makes him obey. Where his allegiance has been once given, there it remains. His _hataman_ is more than a superior officer; he is the chief of the clan, the head of all the tribe, and the subordinate is united to him by the traditions of centuries of mutual dependence. Where other than blood-kin officers are put over the Cossack he mutinies, as when, in Manchuria, Petersburg-schooled lieutenants were drafted and raised to command. But give him his own rightful chief, then if the Cossack is told to do something it is done. He will cross himself and jump from the tower, as in Holland did Peter the Great’s guardsman at the word of the chief to whom he had given his loyalty.

The savage valor of the warriors in Verestchagin’s picture, _The Cossack’s Answer_, is typical of the spirit of these soldiers. Surrounded by battalions of the foe, fated to annihilation when the summons to surrender is rejected, the leaders, laughing uproariously in approval, hear their _hataman_ dictate the insulting reply that dooms them all. If one would ride to China he can have no better guards and comrades than the Cossacks.

We are close to the border now, climbing the last crest which separates the Chickoya from the Cellinga Valley, our toiling tired ponies white with frost. All day the long sweep of the hills has been taken through heavy snow. The landscape is barren, desolate, and lifeless save for the occasional sight of a distant Buriat horseman. The sun is slowly sinking.

The crest at last! The driver points with his whip to the dark masses of houses below, wreathed in the curling smoke of the evening fires. Here and there is a brilliantly painted building or tower, and sleighs and horsemen are passing in the streets. “Troitzkosavsk!” he says. He points further ahead to another more distant town, whose most dominant features are the great square tea-caravansaries and a mighty church, green-domed, with a gilded far-glimmering cross. The huddled houses end sharply toward the south, as if a ruler had marked off their limit in a straight stretch of white. Along this pale are little square sentry-boxes, striped black and white. In the evening sun a distant glint of steel flashes from the bayonet of a pacing sentry. “Kiahta!” the driver says. Then, across the white strip where a wooden stockade girds a settlement of gray-walled compounds, fluttering with tiny flags, gay

with lofty towers and temples flaunting their red eaves, he points a third time: “Kitai!” (China).

He picks up the reins, and lifts the whip; “Scurry!” he cries to the horses. The ponies leap forward, throwing their weight against duga and collar, and we sweep down the hill toward the nearest Russian town, Troitzkosavsk, four versts from the border.

As we come down to the main road hard-by the town, officers of the garrison drive past with their spick-and-span fast trotters, city-wise, as one sees them in Irkutsk. Behind rolls a Mongol cart driven by a burly Chinaman. A Buriat, come to town to replenish his supply of powder and ball, follows on his shaggy pony.

Down a long street, flanked first by log cabins with courtyards and fences like those in the peasant villages, then by stucco-plastered houses, cement-walled government buildings, and great whitewashed churches, we pass and reach the centre of the town. Then we turn up a side street to the house of a mine-owner, to whom we are accredited.

Nicolai Vladimirovitch Tobagov meets us at the door of his log house, clad in gray flannel shirt and knee-boots. A not unnoteworthy product of Siberia is this man,--squarely built and yet wiry, with nervous strength expressed on his bearded face. He is self-made, risen from the masses. A peasant-boy, he started life as assistant to a surveyor, learning to read and write by his own efforts. During this apprenticeship he studied his chief’s books on geology, by the light of the brands for the samovar in the peasants’ houses where they were billeted nightly.

He located placer gold in a number of spots, at a time when the oblast was a lawless “no man’s domain,” without any legal means in existence for acquiring title to property. Guarding in silence his secret, he waited years, until at last a mining-law was enacted for the oblast where his prospects lay. When this law ultimately made private ownership possible, he started in to realize. A friend lent him the money for a mill, which he constructed, according to book-descriptions, on the model of those in California. At first it failed to work, and broke again and again. His riffles were set too steeply. They had let the gold scour away, and his neighbors reported that there was no gold to collect. But he fought it through to victory, returned every borrowed kopeck with interest, bought new machines, and prospered; till now, besides controlling several mines, he possesses a great domain in the river valley, some hundred versts away, with fields of wheat and rye and hay-meadows.

When the visitor has stamped the snow from his felt boots and emerged from his shaggy bearskin coat and hooded fur cap, he enters the main room, with its walls of great logs bare of ornament and showing the scorings of the axe, but clean as new-planed wood can be. Between the chinks straw and moss are packed to keep out the cold. Two great benches flank the sides of the room. Not a picture, not an ornament, not a curtain, not a drapery, not a shelf, breaks the plainness of the log wall, but here and there are hung guns and rifles. In essentials this large house does not greatly differ from the typical peasant’s dwelling. But a copy of the “Sibir” newspaper lies on the table, and photographs of the female members of the family are added to the many reproductions of relations in military dress, which the photographer has touched up with brilliant dashes of red, to pay tribute to the coat-lining, and white to indicate the gloves. Lamps replace the lowly tapers, and they burn before more gorgeously gilt ikons. The windows are double, with cotton-wool and strips of colored paper between. This is a great improvement on the single ice-crusted window, with its perpetual drippings down along the sill. There are the little sheet-iron stoves, whitewashed after the tradition of the oven; chairs with backs, as well as the square stools; and small rooms curtained off from each other. A clock hangs on the wall, and there are carpets on the floor. A large table stands at one end, on which is the ever-boiling samovar, which is nickel instead of brass.

We are made acquainted with the wife of the host, a stout matron of fine domestic proclivities. Though of humble origin, she has discarded her peasant shako and bandana-handkerchief headdress for a bonnet, and dispenses, as to the manner born, many luxuries. On the other hand, she has lost the robustness which keeps her peasant sisters fresh and hearty. Sewing-machines, and beds, and servants, must exact toll even in Siberia. Her boys are clean-cut and intelligent. They go to school and are the future “Intellectuals” that are seeding Siberia. Sixteen children--eleven Nicolai Tobagov’s own, five adopted in open-hearted generosity--sit down to four very solid meals a day in the big hall. Ivan Simeonski, _optovie_ and _argove_ merchant, and Nicita Baeschoef the lieutenant, traveling west on furlough, are stopping in this friendly house, and many other guests are here. The hospitality of the household is conducted on a scale of patriarchal magnificence.

Before our furs are fairly off, the host has called aloud for _obeid_. One’s first formality is, as usual, to salute the ikons and the guests. One’s second is to escape the scalding vodka, seventy proof, and then begin with the _zakuska_ of ten cold dishes on the side table. There is black caviar from the Volga, though the rapid diminution of the supply has raised the price to ten roubles a pound. There is red caviar from the Chickoya, cold mutton, cold sturgeon, sardines, ham, and sliced sausages made at home. The latter must be abundantly and appreciatively sampled, because they have been specially prepared under the direction of the

souprouga herself. One stands before the _zakuska_ and dips from dish to dish. Next, the guests take the square wooden stools and draw up to the great table, where the plates are set for the real dinner. Each one helps himself to the smoking soup, which is passed in the tureen. As this is being ladled, a plate of round balls comes by, the delicious _piroushki_, dough-shells filled with hashed meat, always served with soup. We have entered upon a typical Siberian meal, with the boiled soup-meat eaten as the second course, and madeira, champagne, claret, and rum, indiscriminately offered. A perfect babel of conversation goes on, and one is pressed to try this, try that, try each and everything of the long menu, under the watchful eyes of the kindly host and hostess.

At all times of the day the samovar is left simmering, ready for any one of the multitudinous household to brew tea, and constantly replenished _zakuska_ dishes deck the sideboard. Guests, attendants, children, and friends come and go in the utmost freedom. Such is the _Hazan's_ life.

In another part of the building there stuffs to repletion an army of dependents. Servants, artisans, drivers from the caravans which pass up from China by the road below the house, a whole other below-stairs world is here. Twenty caravan teamsters, _karetniki_ or _isvoschniki_ of the sledges and carts that fill the ample courtyard, huddle in the back rooms for tea. An old bespectacled maker of string-net doilies, who reads Alexander Pushkin's poems, is working out a week's board in the room where the chickens are kept. The housewife does not disdain, either, to find a place for the traveling _sapojnik_, who will put leather reinforcements on the felt boots which have been worn through at the heel. It is a large easy way of living, this of the man who holds a leading place in the border city.

[Illustration: A CHICKOYA GIRL]

[Illustration: TROITZKOSAVSK STUDENT]

A mixture of crudeness and culture, of luxury and hardship, of Orient and Occident, runs through the quaint fabric of frontier society, with its medley of races and types. Fine avenues flanked by stuccoed houses pierce the main city. Back of them lie the log houses of the plainer citizens, while the outskirts are occupied by the felt huts of the Buriats and Mongols. Students in uniform elbow Cossacks of the Guard, and maidens from the seminary brush the Mongol wood-choppers.

"Téatre?" suggests one evening the twenty-year-old son of your host. Of course the invitation is accepted. At eight o'clock you put on your felt boots, and tramp down past dark-shuttered log houses and the silent white church into the field, where stands a barn-like building placarded with the programme. The young guide secures seats at the ticket-counter of rough lumber. Seventy-five kopecks they are, each. With them are handed out eight numbered slips of red paper. Then together you break a way to the front rows, through the crowd of burly Cossacks of the garrison, bearskin-capped students, citizens with shiny black boots, and here and there a husky stolid-faced Buriat. Keeping hat and coat on, as does every one else, we find seats on the rough benches wheresoever we like or can; for nothing is reserved save the elevated perch of the musicians, where a four-piece orchestra drones out a monotonous Russian march. What a fire-trap! is the first thought. To each of the posts that sustain the rafters is fastened a lamp shedding an uncertain light on the hangings of bright-red cotton cloth, in dangerous proximity to which, utterly disregarding the "no smoking" signs, stand the crowd of forty-kopeck admissions, rolling and smoking perpetual _papirosi_.

As the impatient audience begins to pound and stamp, a bell rings, and the curtain rises on two comic characters busily engaged in packing for a hurried departure from their lodging. The stage has become a room, with red-cotton-covered walls and bright green curtains. A merchant comes with a bill for comestibles six months due. He is quieted with extravagant tales of forthcoming change for a hundred-thousand-rouble note. The landlady enters, and the shoemaker's apprentice with a pair of mended boots. Both are likewise cajoled and bullied away. The Jewish money-lender is more difficult, but at length, to the manifest delight of the audience, he, too, is staved off, and the pair draw the vivid green curtains and go out through a window for parts unknown, amid much glee and applause.

We now go out to the "buffet" and contribute to the dangers of conflagration by smoking an offered cigarette. We also add to the theatre's income by buying a glass of hot _chai_ for ten kopecks. Something special is in the air for the next act. The audience is buzzing and moving in eager expectancy. We return to our seats. The curtain rises upon a double row of two-_pud_ (sixty-four-pound) weights, such as are used at the bazaar to sell frozen beef. Amid a thunder of stampings on the plank floor one of the escaping debtors of the last act, dressed in tights, comes out from behind the green curtains, and lifts one of these above his head. Then he poises one with each hand. Finally a wooden harness is adjusted to his body, and sixteen weights (or about half a ton), are heaped upon him by the jack-booted Buriat stage-attendant on one side, and the defrauded merchant of the first play on the other. It is the most unspectacular performance possible, this athletic test, but it takes the place of a football match in Siberia.

The applause is ferociously appreciative.

More _chai_ and cigarettes, and we come back to hear a very pretty girl, dressed in the peasant's costume of Little Russia, head a chorus, and to see a boy in red blouse and boots dance the wild dervish whirl which the peasants of tradition are supposed to execute. The boy is in the midst of his performance when there is a tumult among the forty-kopeckers under the musicians' eyrie. The latter, being human, try to watch what is going on below and play jig-music at the same time, and sharps and flats fly wide of the mark till the sounds become frightful. Everybody jumps up on his bench to see a peasant having a turn with a Buriat, and further trouble brewing with a Cossack who has got upset in the mêlée. There is a chaos of tossing hats and brandished fists, and the two armed soldiers who are on guard as policemen press in, with gruff shouts to make them way. The tumult finally goes out the door and into the street, and we turn back to the poor dancer still trying to beat out his stunt.

The curtain rises next on the manager, who has been up to date weight-lifter, escaping boarder, and part of the peasants' chorus. He is seated at a table, looking very ordinary in his street clothes. Behind him is another table covered with an assortment of crockery, mirrors, spoons, vases, pieces of cotton cloth, and a big striking clock. He calls for a volunteer from the audience for some unknown purpose, and a little rosy-cheeked uniformed Buriat schoolboy, who has been peeking behind flapping curtain between the acts, responds. The boy reaches into a box and pulls out a slip of paper. The manager reads a number from it, "_Sto piatdeciet sem_." An eager voice from the rear answers "_Jes!_" The stage-attendant takes a glass tumbler from the table and carries it solemnly to the man who has answered. Your host nudges until you comprehend that you are to excavate the eight theatre-slips, which you do, to find that two only are seat-tickets. The rest are numbered billets, and you are liable at any moment to receive a perfumery-bottle or a candlestick from the lottery which is in progress. The scene now takes on an imminent personal interest shared with the banked forty-kopeckers behind. A breathless strain accompanies the drawing of the numbers. It mounts to a climax as the big musical clock is approached. The fateful billet is at last drawn in intense silence. Every eye is fixed on the reader. Not a Cossack speaks, not a Mongol moves.

"_Dvesti tri!_" and a sharp "_Moi!_" tells that the clock goes to ornament the table of a burly peasant, who grinningly receives it. The tense breaths are let out, the forms relax, and the crowd straggles to the door, lighting cigarettes and pulling down caps. The drama is over. Next morning at eight a soldier visits your host with a message from his chief.

"Bring to the police-station the passport of the stranger seen with you at the theatre last night."

A town droshky will take one the few versts to Kiahta, where in the Geographical Society's museum is the celebrated sketch of the Dalai Lama made at Urga by a Russian artist, when the young Tibetan monk had fled before the English expedition to Lhassa. Here, too, are ore samples and reconstructed Mongolian tents. But it is hard to look at fossil rhinoceros-heads and at stuffed sabre-toothed tigers and musk-deer when the camel-trains are passing and China is a verst away. A courier is necessary now, for resourceful Jacov and driver Ivan are strangers beyond the border. Perhaps our host knows of a man acquainted in Mongolia? He will inquire. Next day there presents himself a slight, bearded, intellectual man, Alexander Simeonovich Koratkov, usually called, for short, "Alexsimevich." Bachelor of forty, educated in the Troitzkosavsk "Realistic" school. He speaks, as well as Russian, Mongolian, English, French, German, and some Chinese. He has translated for the English engineers who were brought in to work the Nerchinsk mines. He is deeply read in Buddhist mythology and sociology. Will he go down into Mongolia with you? Yes; and so it is arranged.

Provisions are cheap and abundant in the Siberian towns. Sixty kopecks buy a pound of caravan tea, seventeen kopecks a pound of sugar, the sort that comes in a cone like a Kalmuck hat. It is a luxury by warrant of public opinion, so much that it has, of note, been served on baked potatoes. Before the Buddha pictures of the Buriats, a few lumps may be the choicest offering. Flour costs six kopecks a pound. Beef, if a great pud-weight forequarter is bought at the market, twenty kopecks. Frozen butter will cost twenty-five kopecks per pound. Eggs, of the Siberian cold-storage variety, forty-eight kopecks a dozen. For thirty kopecks one gets a piece of milk as big as one's head. But do not try to go beyond the native produce, for canned goods, coffee, or sardines. It is bankruptcy speedier than buying bear-holes. A big magazine will sell pâté de foie gras, imported from France, at two roubles the tin; while beneath the Chinese caravansaries' arcade, bales of tea will be sold at a few kopecks a pound. One gets cigars in a glass-covered box, with the government stamp, for a rouble and a half, and they will be worth about as much as the strings of twisted tobacco-rope which the Mongols carry off as their single cherished luxury.

And now for transportation. The sledge can serve no more, for the snow goes bare in places along the caravan trail. We must have a tarantass, and in time one is produced for inspection. A cask sawed in half, lengthwise, is the image of its body, a lumber-cart the

model of its clumsy wheels and framework. To the tarantass is hitched the trotter, with his big bow yoke to bring the weight of collar and shafts on his back rather than against his neck. At each side of him, with much such a rig as is used to tow canal-boats, are made fast the two galloping horses.

When one goes beyond the post-route with his own equipage he has, fastened under the driver's seat and behind his own, bags of oats and hay, which must serve as emergency-rations for the horses against the days in which none can be secured along the often deserted trail. Personal provender must be likewise stored away, bags of bread, frozen dumplings to make soup with, tea, sugar, milk-chocolate, milk, candles, cheese, matches, kettles, and whatever else one can think of, or that the ingenuity of Alexsimevich can devise. Hay is piled into the tarantass bottom to supply the want of springs.

A driver who knows the trails has been found, André Banchelski, a tall Siberian, of timbering and hunting antecedents, who has a small stock of Mongol idioms regarding the price of hay and the location of water. He has reached a very good understanding with Katrinka, one of the household dependents, and Nicolai is taking an interest in him.

To-night we go to sleep on Nicolai's plank couch, ready for the march of the next day. All is ready. To-morrow we cross the Chinese frontier.

V

IN TATAR TENTS

The shaggy ponies, white with the frost of the morning, stand harnessed to the tarantass; André in his belted sheepskin _shuba_, whip in hand, is perched on the bag of oats; Alexsimevich sits in a greatcoat of deerskin, with only a nose and a triangle of black beard visible. The host, in his gray surtout, and the red-bloused drivers of the sledges scattered in the courtyard, all have left their samovars to see the start. The children of the family peep from behind the mother with her gray shawl-covered head. They group at one side, under the eaves of the doorway, while Josef, one of the household servants, swings back the ponderous gates. The reins are drawn in, the whip is lifted, the horses are leaning forward into their collars, when the cry of "André!" comes through the opening doorway.

From behind the gathered onlookers, who turn at the sound, runs out Katrinka, dressed in her best red frock. "André!" she cries. He pulls back the starting horses, and Katrinka lifts up to him a little bag embroidered with his initials in blue and red. "For your tobacco."

He looks down into her eyes and smiles. "_Spasiba_ _loubesnaia_," he says, and pushes it into the breast of his shuba.

"_De svidania_, André!" she whispers, then runs back, confused.

The teamsters laugh, pleased and amused as big children at her blushes, and her brother shouts a commentary from the gateway. "_Vperiod! vperiod!_" says the interpreter. He has reached forty now without falling before the charms of any Siberian girl, and he does not sympathize. "On! on!"

The horses swing out of the great gateway into the snowy streets, with "Good-bye! Good road!" called in chorus after us.

At a slow trot the lumbering carriage rolls through the quiet town, misty in the cold of the morning. The row of shuttered shops, with their crude pictures of the wares within, are opening for the day. The little park with the benches, which are trysting-places of summer evenings, cushioned now with six inches of snow, and the low log houses beyond, loom up and retire rearward, as we pass. The white church and the fenced cemetery of Troitzkosavsk are left behind, and we are on the broad paved road by which a sharp trot of half an hour brings us to Kiahta.

Its scattered houses now in turn begin. The big tea-compound, of four square white walls, flanks us and is gone. The officials' residences and the barracks of the garrison appear and vanish behind. The street opens out into a big square, where, shimmering against the white ground, stands the great church of _Voskresenie_, the Resurrection. On its green dome, lifted high in appeal and in promise, gleams the gilded cross. In white and green and gold Russia raises inspiringly the symbols of Slavonic faith before the doors of the heathen empire. As we pass the white Russian church, the litany of the popes and the answering chant of the choir come faintly wafted from within. But even as the Christians sing, the clash of distant cymbals and the roll of a far-off prayer-drum meet and mingle with the echoes. On the hill across the border, in vivid scarlet against the snow, with painted walls, sacred dragon-eaves, and flapping bannerets, flames a Chinese temple.

Here now is the borderland of empires. The neutral strip is in front, a hundred _sagenes_ broad. The Cossack sentries stand at ease before their striped boxes, which face toward Mongolia. Far to the east and far to the west are seen stretching the long lines of posts marking the boundary. The outmost sentry, as the tarantass rolls across the strip, hails you with a last "_De svidania!_" (God speed!)

Past the Chinese boundary-post, covered with hieroglyphic placards and shaped like the lotus-bud, we drive, and in under the painted gateway of the gray-plastered wall. No Männlicher-armed Chinese regulars, like those that in Manchuria throng to hold what is lost, guard this half-forgotten road. No sentry watches; no custom-officer bids the strangers stop. Through the open gate we ride into the narrow street of the trading city of the frontier--Maimachen, the unguarded back door to China.

In life one is granted some few great impressions. None is more striking than that experienced in passing beneath the shadow of this gabled gateway. Behind are kindred men, the manners of one's own kind, police, churches, droshkys, museums, theatres, the whole fabric of European civilization. From all these one is cut away in the moment of time taken in passing the neutral strip. Two hundred yards have thrust one into the antithesis of all western experience, into an utterly strange environment, where the most remarkable of the world's Asian races lives and trades, works and rules.

Everything which is made sensually manifest by sight, by sound, by scent, by action, is weirdly alien. You three in the tarantass are as men from Mars, isolated, and moving among people foreign to your every interest and experience. The solitary strangeness of your little party in the tarantass, started into a forbidding land, the first confronting vision of the eternal Orient--these are the things for which men travel.

As you go slowly down the narrow lane-like street, you catch glimpses of banner-decked courtyards seen through great barred doors in the gray mud walls. Here and there a sallow blue-coated Chinaman, with skull-cap and queue, passes by, his folded hands tucked into his long sleeves, fur-lined against the cold. Chinese booths and shops are open. Waiting traders, seeing yet invisible, behind the many-paned paper windows, look outward through the peep-hole.

In the city square a halt is made before a Chinese store, for a last provisioning. At the entrance half a dozen Russian sledges are drawn up. Here can be had the supply of small silver coins indispensable for the road, canned goods of European origin, and a bottle whose contents may be less like medicine than is vodka. Though the goods come all the way from Peking on camel-back, they are much cheaper than the tax-burdened provisions over the border in Russia. Indeed many of the main Chinese stores, with their surprising stocks of wines and pâtés de foie gras, candies, and Philippine tobacco, are supported by Russian inhabitants of Kiahta and Troitzkosavsk. It is amusing to watch the enveloping of champagne-bottles in sleigh-robes, and the secreting of cigars beneath fur caps for the return journey.

We stroll a little way down the street, among the Chinese booths for native wares, where sturdy shuba-robed Mongol tribesmen are bartering sheepskins for blue cotton cloth, metal trinkets, quaint long-stemmed metal pipes, and wool-shears with big handles. They are probably getting deeper in debt, as usual, to the wily traders. We pass the haymarket in the shade of a ruined temple, where the Mongols have heaped their little bundles of provender.

All the while one has an eerie undefined sentiment that something is lacking. It is not that the houses which face the narrow main street are low and poor, that the gray mud-walled compounds are grimly unwelcoming with their closed iron-studded gates. It is not that the small stocks of goods in the shops tell of a vanished prosperity, now that the bulk of the tea-trade has left. It is not anything material, but an oppressive indefinable feeling that something is lacking. Only when Alexsimevich makes a chance remark, do you realize consciously what it was you instinctively felt, "It is queer to be in a city where there is not a woman or child."

Some have explained the exclusion law which controls the situation by the self-sufficiency of the Chinese, who wished no real settlement of their people here,--the fruit of a pride deep-rooted as that underlying the custom which brings every corpse back to China for burial. Others, by the desire to avoid transmitting to the Empire the diseases that are rife in Mongolia. Whatever the basis, the regulation is in full force to-day. At one time merchants in Maimachen kept their wives across the border in Russia, which under a subterfuge was not technically forbidden. But the ability to hide behind a technicality is a blessing enjoyed especially in democracies. It did not go with the chief of police, who came down for a squeeze which made it more profitable to pay the women's fare home than to continue to offend.

[Illustration: A WAYSIDE TEMPLE]

Associating with the native Mongol women is here precluded by the fact that there are no settlements near by from which the Chinese might get indigenous consolation. A deserted tract lies behind the town. Only camel-drivers, wood-cutters, and sellers of cattle come into Maimachen, and they leave at night. For though the Mongols, in their pointed hats, pass along the streets, none may lawfully live within the stockaded walls, and none keep shop beneath the carved eaves of the houses which flank its narrow streets. This is the prerogative of Chinese traders from beyond the far-off Wall.

The spectacled merchant Tu-Shiti, who has become prosperous from the sale of Mongol wool, retakes for a visit, every two years, the long camel-trail to Kalgan and China. The tea-trader, Chantu-fou, drinks his wares alone. The slant-eyed clerks and booth-keepers trotting down the streets in their skull-caps, hands tucked up the sleeves of their blue jackets, plan no theatre-parties or amity balls, or sleigh-rides in the biting air, as over the way in Kiahta. The seller of sweetmeats will never be told to be sure and inclose the red and black New Year's card. There is no red-cheeked Chinese boy to smile as he munches your sugar; to puzzle over your ticking watch as at Kotoi, or to tease the tame crane in the courtyard. Not a girl appears on the narrow streets. It is the sentence passed upon the generations of Chinese who have gone to Mongolia, that no woman of their race shall pass the Wall. And so it must remain, for never a home will be founded till China, the unchanging, shall change.

Back and forth through the thoroughfares go the little men with the queues flapping against their backs and their sallow uncommunicative faces. Are they thinking of the time when they will have made their little fortunes and can get back to China to enjoy them? As they wait for customers in the little booths, do they plan the homes which none of their blood may ever possess in Mongolia? When they sleep on their wooden platforms, do they dream of faces in the Kingdom of the Sun? Never will one know. Around the thoughts of the Chinaman arise the ramparts of his isolation. What he believes, what he hopes, what he dreams are not for you. The soul of China is behind the Wall.

The tarantass rolls out of the quaint weather-worn gateway of the woman-less city of Maimachen. "How much they miss!" says André, filling his pipe from the new pouch. "How much they escape!" retorts Alexsimevich.

When in hot haste Pharaoh ordered out his great war-chariot to pursue the rebellious Children of Israel, and thundered through his pyloned gateway with plunging horses urged by the shouts of his Nubian charioteers, he must have experienced, despite contrasts, much the same physical sensations as those which we feel when the tarantass starts in full gallop across the level plain to the distant range of mountains; but where Pharaoh's robe was white with dust, ours is white with snow, and the sun, which baked his road, makes ours endurable.

The horses leap free under the knotted lash of the Siberian driver. With the rumble of low thunder the ponderous wooden wheels bound over the rutty road, hurling the springless tarantass into the air and from side to side. You brace yourself with baggage and hold to the sides, but toss despite all, like corn in a popper. The hay on which you sit shifts away to one side, leaving the bare boards to rub through clothes and packs. A sudden splinter makes you jump like a startled deer beside the way. In this noisy tarantass, down the narrow road grooved with the ruts of the Mongol carts and sledges that have gone northward, you tumble and groan and bump and roll out across the open country.

There is a wide plain from Maimachen. It climbs into the first barrier-range and the forest belt of Mongolia, whose plateau is the third terrace in the rise of land from the low frozen flats of the Northern Lena to the Roof of the World,--the Himalayas of the south. The northern city of Yakutsk is at a very low elevation, only a few feet above the sea. Irkutsk on the fifty-second parallel is 1521 feet in altitude, Troitzkosavsk on the fifty-first is 2600, Urga on the forty-eighth 3770, Lhassa 11,000 feet.

Far to the northwest, Mongolia is a forested fur region; far to the south is Shama--the desert. Here at the north and east the forested belt of the Siberian highlands south of Baikal breaks off almost at the boundary.

Snow is over everything, but thinly. It has been worn away on the road, leaving brown patches over which the tarantass, mounting the long slope with horses at a slow trot, lugubriously thuds. A long stretch of straggly trees and stumps tells of Kiahta peasants going over the border to cut wood where no timber-laws limit. Up and up we go, the way steeper every _sagene_,--afoot now and the horses leaning and pulling at the traces. Finally silhouetted against the sky appears a rough pile of stones. At its top bannerets are waving from drooping poles. It is the Borisan on the summit of the pass to which every pious Mongol adds an offering, until the pile is many feet high, with stones, sticks, pieces of bread and bones. Some throw money which no one save a Chinaman will commit the sacrilege of touching; some give a Moscow paper-wrapped sweetmeat, some a child's worn hat or yellow-printed prayer-cloths waving on their sticks and fading in the wind;--everything is holy that is given to the gods.

A piercing wind, searching and paralyzing, meets the tarantass beyond the crest at the southern border of the forest: it is Gobi's compliments to Baikal, the salute of the great desert to the great lake. The horses stumble through the drifted snow, scarcely able to walk. The driver, blinded, half-frozen, keeps to the general direction of the obliterated trail. Barely one verst an hour is made, until, under the shelter of the bald white range of hills, the road reappears and the wind is warded off.

A rolling plain between the heights is the next stretch of the way. The afternoon sun, dimly bright, creeps haloed through the lightly falling snow. Deep in the mist appears a dark moving mass. It grows, focuses, and takes shape into a shaggy beast of burden, and camel after camel emerges from the haze, loaded with square bales of tea.

"Ask if there is shelter near," you shout to the muffled head of the interpreter.

"I will ask," he replies. Then to the caravan leader: "_Sein oh!_" he cries in greeting.

The foremost camel stares stonily as its Mongol driver twitches the piece of wood which pierces its upper lip, and the whole train stops.

"_Gir orhum beine?_"

"_Ti, ti, orhum beine!_" comes the answer. "It is close at hand."

Forward the caravan slowly paces, each camel turning his head to stare as he passes out into the mist again. One of them has left a fleck of blood in each print of his broad spongy foot which the driver will cobble with leather at the next halt. Along their trail you drive southward. The mist is clearing as you rise, and the sun shines down on the snow which has crystalized in little shafts an inch high. These spear-shaped slivers have a brightness and a sheen of extraordinary brilliance, and like prisms show all the colors of the rainbow. They cast a gleam, as might a mirror, a hundred yards away. It is as if upon the great white mantle had been thrown haphazard treasuries in rubies and emeralds and diamonds and opals,--myriad evergrowing rivals of Dresden regalias. The sun goes down with its necromancy. Beyond, the soft blanket enfolds the rolling hills. It drapes the rocks and weaves its drooping festoons about the barren mountain-sides.

"Mongol _yurta_!" calls André, turning to point out with his whip the low dome-shaped hut, black against the darkening sky. On its unknown occupants we are to billet ourselves, sheltered by the rule of nomad hospitality. As the tarantass nears the wattled corral, the watchful ravens stir from their perches. The picketed camels turn to stare. A gaunt black hound stalks out, with mane erect and ominous growls.

"_Nohoi_," cries out Alexsimevich, to the inhabitants of the hut; then adds to you, "Very bad dogs! It is a Mongol proverb: 'If you are near a dog, you are near a bite.'"

Beneath an osier-built lean-to a woman is milking a sheep, with a lamb to encourage the flow. She calls a guttural order to the dog, which slinks back. Then she comes to the wattled fence, while the sheep which has been getting milked escapes to a far corner of the yard. The woman's head is curiously framed by a triangular red hat, and silver hair-plates, which hold out like wings her black tresses. The shoulders of her magenta dress are padded up into epaulettes two inches high. She is girded with a sash.

"_Sein oh!_" says Alexsimevich.

"_Sein!_" she answers, and opens the gateway to the enclosure around the hut.

André drives in among the sheep and cows, and you climb lumberingly down with cold stiffened limbs. André puts his whip upon the felt roof, for it is a deadly breach of etiquette to bring it into the house.

"You go in," said Alexsimevich.

It is like entering a kennel, this struggle through the narrow aperture, muffled to the eyes in double furs and awkward felt boots. As you straighten up after the crawl through the entrance, a red glare from the fire just in front meets the gaze. Stinging smoke grips the throat; you choke in pain. It blinds the smarting eyes. You gasp and stagger. Then some one takes your hand and pulls you violently down on a low couch to the left, where in course of time breath and sight return. There is no chimney, nor stack for the fire of the brazier, which stands in the centre of the hut. One can see the open sky through the three-foot hole above. The smoke, finding its way toward this aperture, works along the sloping wooden poles which form the framework of the felt-covered tent, filling the whole upper section with its blinding fumes. To stand is to smother. Sitting, the head comes below the smoke-line.

With recovered vision, one can look around within the hut. The couch of refuge, raised some six inches above the floor, is the bed by night, the sitting-place by day. Against the wall at the left hand, and directly opposite the door, is a box-like cupboard, along whose top are ranged pictures of grotesque Buddhist gods, before whom are little brass cups full of offerings, millet or oil, in which is standing a burning wick. Beside the door is a shelf loaded with fire-blackened pots and kettles. Branches of birch for fuel are thrown beneath. On the far side of the room, three black lambs, fenced off by a wicker barricade, are huddled together, quietly sleeping.

[Illustration: A MONGOL BELLE AND HER YURTA]

[Illustration: A ZABAIKALSKAIA BURIAT]

Seated beside the fire close by is the girl of nineteen who has just saved you from asphyxiation. The long fur-lined working-dress, common to all ages and sexes of Mongols, is buttoned on her left side with bright brass buttons, and is belted in with a sash. She has not the padded shoulder-humps, nor the spreading hair arrangement, which gave to her mother, who welcomed us, so weird an appearance. Her complexion is swarthy like an Indian's, not the Chinese chalky yellow, and she has red cheeks and full red lips. Her eyes are large and black. The rest of the party have stayed a moment outside to ask about hay and water. You have made this solitary and awkward entrance. The girl has no more notion than a bird who the strange man of another nation may be, who has stumbled into her home. But it does not trouble her in the least. For a moment she looks you over calmly, with a smile of amused curiosity, rolling and wringing with her fingers a lambskin which she is softening. Then composedly she bids you the Mongol welcome, "_Sein oh!_" and holds out her hand. Her grip is as firm and frank as a Siberian's.

Now Alexsimevich comes tumbling through the door, and next André. Both are used to these huts, and artistically stoop below the smoke-line. All our impedimenta--blankets, furs, pots, kettles, bread-bag, rifles--are heaped in a mound within the space between the couch and the tethered lambs. The girl has not stirred from her work.

"They are friends of yours then, Alexsimevich?" you ask.

"No, no, I never saw them," he answers. "Any one may take shelter in any _yurta_ in Mongolia."

A small head suddenly makes its appearance from the pile of rugs on the sofa opposite on the women's side of the tent. There emerges, naked save for a bronze square-holed Chinese _cash_ fastened around her neck, a little slant-eyed three-year-old. The water in the small cups offered to the _dokchits_ has long been ice, and one has full need of one's inner fur coat and cap in the hut, where the entrance, opening with every visitor, sends a draft of air, forty degrees below zero, through from the door to the open hole which serves as chimney. And still this tot can step out naked and not even seem to feel it.

"The child's name?" asks Alexsimevich.

"Turunga," replies the girl.

"And your own?"

"Sibilina," she says, and smiles.

Turunga carefully inspects you, and solemnly accepts a lump of sugar which she knows what to do with, even if it is a rare luxury offered to gods. She sits down, in an evidently accustomed spot on the warm felt before the brazier, to play with the scissors-like fire-tongs, carefully putting back the red coals that have fallen out on the earthen platform.

The tarantass-driver, having piled up your impedimenta, excavates from its midst the bag of rye-bread, which he sets to thaw. He gets next the little bag of _pelmenes_, the meat-balls covered with dough-paste which you carry frozen hard. The mother comes in from under the _yurta's_ flap, and, placing a blackened basin over the brazier, puts into it a little water and scours diligently with a bundle of birch-twigs. She brushes out this water on the earthen floor near the entrance. This is the picketed lamb's especial territory, to which the felt rugs before the couches and the altar do not extend. A big bag of snow which she has brought from outside is opened and the chunks are piled into the basin, where, while one watches, it melts down into water.

"_Boutzela! boutzela!_" she cries soon, holding a lighted sliver over the basin to see by: "it boils." Into the Mongol's pot go our _pelmenes_, to brew for a few moments. An accidentally trenchant description of Siberian _pelmenes_ was given on the quaintly-worded French bill of fare in the hotel at Irkutsk: "Meat hashed in bullets of dough." They come out, however, a combination of hot soup and dumplings, very welcome after the long cold day's drive across the plains, the frozen marsh, and the

rolling hills. The wooden Chinese bowls from the bazaar at Troitzkosavsk are filled now with our hostess's big ladle, and the application of warmth inwardly gradually thaws the outlying regions of the body.

But there is trouble in camp. Turunga is moved by the peculiar passions of her sex and her age, curiosity and hunger. It does not matter in the least that she has home-made _pelmenes_ every two or three days--she wants these particular meat-balls. The little mouth begins to pucker and the eyes to screw up. No amount of knee-riding by the mother takes the place of the _pelmenes_. We fill a heaping ladleful and André furnishes his own bowl. The mother receives it, holding out both her hands cup-fashion as is the etiquette, and Turunga is satisfied.

The mother looks kindly to the stranger and smiles at André, then throws more sticks of the precious firewood on the embers. André has caught, likewise, the not unadmiring glance of the young maid. The girl who waits in Troitzkosavsk is not the only one who appreciates our six-foot Siberian hunter.

The dog barks in the yard, but without the menace which hailed us, and the crunch of a horse's hoofs sounds on the frozen ground outside. The flap opens, with its inrush of freezing air. Stooping, there enters a typical Mongol, squat of figure, round of head, with broad sunbrowned face and a short queue of black hair. He wears a funnel-shaped hat, magenta-colored, and is enveloped in a long _shuba_, with brass buttons down one side like a fencer's jacket. About his waist is a sash with jingling knives and pouches. He is the head of the family, come in from herding his horses. He turns back the long fur-lined cuffs which have protected his gloveless hands, and stretches out both his arms for you to place your hands over his. It is the man's ceremony of welcome. Then he produces a little porcelain snuff-bottle. This must be received in the palm of the right hand with a bow. It is to be utilized, and passed back. If the herder is out of snuff, the bottle is offered just the same and you must appreciatively pretend to take a pinch. Such is etiquette.

The soup is gone now; the pot, cleaned out for the tea, is again on the boil and the leaves are thrown in. André has borrowed a hatchet from his host, and has chopped off a piece of milk, which goes in as well.

It is in order to ask the new arrival, Subadar Jay, to pass his wooden cup for some of the beverage. He takes it and the lumps of sugar without a word of thanks. The Mongol language has no expression to signify gratitude. Silence does not, however, mean that he does not appreciate. The dozen pieces of Mongol sandal-sole bread which he gives you later are worth two bricks of tea in open market, and this current medium of exchange--caravan-brought tea--is worth sixty kopecks the brick. No small gift, this bread, to an interloping stranger who is brewing tea by his fire, and camping unasked on his bed. A Tibet-schooled lama knows the Buddhist maxim, "Only accomplish good deed, ask no reward." But the unlettered Mongol layman knows its practice.

Little Turunga has played naked before the fire long enough now; she is caught up; her reluctant feet are put into the boots with pointed upturned toes, and her body into a miniature sheepskin "daily," such as her mother and father wear. The little girl is as smiling and shy and coquettish as any child of white skin and complex clothes.

"Will you sell Turunga for a brick of tea?"

"No, no," says the mother, gathering the little one quickly up into her arms, while the rest of the family smile at the offer and her solicitude. "No, no, not even for ten bricks!"

Everybody laughs, Turunga with the rest, in a child's instinctive knowledge that she is the centre of admiring attraction.

Far more petting than the Russian babies get is lavished on the little Mongols. Perhaps the much smaller families (only two or three children to a hut) allow more attention per capita. The mother hands Turunga over to her father,--unheard-of in Siberia,--and he plays with the child, giving her pieces of sheep's tail to eat from his mouth, answering her prattle or baby-talk and endless questions. At night, about eight o'clock, the mother takes the child to the couch and they both go to sleep, Turunga cuddled warmly under her mother's _shuba_.

Meanwhile we men sit cross-legged by the fire and talk of many things,--of the pasturage for the sheep, of the snow on the road, of the beauty of the housewife's silver headplates, of water and roads, of whether or not the Mongol _dokchits_ on the altar are like the Gobi wolves that hate Chinese.

It is interesting to note how some of the words used (few, however) have a familiar sound--although there is said to be no common ancestry with the Indo-Germanic tongues; perhaps it is only the instinctive sound-imitation which makes the Mongol baby cry "Mama" to its mother, as does the child in Chita and in Chicago. "Mine," for instance, is _mina_; "thine" is _tenei_. A horse or mare

is _mari_. The word for “it is,” “they are,” is _beine_, a fairly respectable form of the verb “to be” in Chaucer’s English.

The grammar is delightfully simple. In the vernacular there is no bothering about singular or plural. “One hut” is _niger gir_; “two huts,” _hayur gir_. “Milk” is _su_, and apparently the word for “water” was formed from it--_ou su_. If one wants to know whether it is time to throw in the meat-balls he says, “_Ou su boutzela?_” with a rising inflection (“Water boils?”) and the answer is, “_Boutzela_.” The “moon” and a “month” are _sara_, and the years go in cycles of twelve. If one wants to compliment the host on the excellence of the sandal-shaped bread which he hands out, loaded with gray chalky cheese (_hourut_), one says, “Bread good be” (_Boba sein beine_); this gives him great pleasure.

Some of the written numbers are somewhat like ours: 2 and 3 are nearly the same, but they have fallen forward on their faces; 6 has an extra tail. When the teapot overturns, they say “_Harlab!_” to relieve their feelings. There is no word for “so good,” “farewell,” or “much obliged.” These are just squeezed into the heartiness of the final “good” (_sein_). So when one leaves, he holds out both arms, palms up, for the host to put his own upon, and says loudly, “_Sein oh!_”

A not unbarren amusement is to study out one’s own derivations for some much-explained words. _Tamerlane_ is often given as meaning “the lame.” Why does it not rather come from _temur_ (iron) and mean “man of iron,” as the ruler of the Khalka tribe was called Altan Khan, the golden king? The Amur River has _khara-muren_ (black water) usually given as its derivative root. Why not the Mongol word _amur_, which means simply “quiet”?

In the hut to-night, while we are comparing mother tongues, the brazier-fire has burned to red brands. The girl reaches into a basket beside the door for pieces of dried camel-dung, and puts them on, that the embers may be fed and live through the night. These _argols_ do not smoke; she may close the chimney-hole with the flap of felt, and the hut will be kept somewhat warm through the night. The Mongols prepare for sleep: they take off their boots, and slip their arms from the sleeves of their fur _shubas_, in which they roll themselves up as we in our blankets. But how hardened they are to the cold! A naked arm will project and the robes become loose, but they do not wake.

We keep on all our inner clothing and roll ourselves about with skins until we are great cocoons. André gives a good-night look to his horses; then he, too, lies down. With our heads beside the altar of the gods, we sleep, in the Mongol’s _gir_.

How cold it is in the morning when we wake! The embers have burned to a gray ash; the iciness of the waste outside has gripped like an octopus the little hut, and sucked its precarious warmth through the night-long radiation. The chimney-hole is open again, and the mother is starting a blaze with her few pieces of birch firewood. André has gone out to harness the horses. He has left the door flap a little wrinkled, and the wind whirls through it and up the chimney, keen as a scimitar.

Alexsimevich is getting out the tea-bowls and the bread. You put a reluctant hand from under the blankets and seize your fur cap. Then you disengage the inner fur coat from its function of coverlet, and struggle, sleepy-eyed, into it. If you have the moral courage to take off these friends in need, and the inner coat and sweater, to get a bowlful of snow-water, and hunt among the baggage for soap and a towel, all at five o’clock in the morning of this freezing weather, then you have full license to call the Mongols dirty degraded heathen. If, however, you sit and shiver, and promise yourself that you will bathe at Urga, it is elementary fair play to be discreetly silent about the little failing of your hosts. You will rejoice, too, in open admiration of courage, when you find, as you sometimes will, a clean-shaven well-groomed lama, or a washed and combed village belle, on the road to the sacred city.

“Ready,” says André. You finish a goodly portion of rye-bread and several bowls of Alexsimevich’s tea, while he is carrying out the luggage and making a pyramid of it in the tarantass. You put both hands out to shake those of Subadar Jay, of his wife, and Sibilina. You give a last chunk of sugar to little Turunga, and crawl out under the tent-flap. The family calls “good-bye” from the gateway as you climb in. Then up the hill you start, for the next day’s ride.

It is slow to travel by this schedule. One can advance by day and rest by night, but daylight travel and night sleep, while most comfortable for a man, are the least efficient for a horse. If progress be the aim, one must adopt the teamster’s system. This involves a start at midnight, and eight hours of travel at a slow trot,--six to seven versts per hour. Then, at eight in the morning, a halt for the ponies. One hour they stand in harness, before getting their quarter _pud_ of hay; after which comes water, and finally, seven and one half _pfunde_ of oats. Four hours of halt are involved, in which one can roll up in his blanket and sleep. Then off again for eight hours of trot, and another four hours of halt at eight in the evening. So the watches go, with some hundred versts made daily.

Noon to-day finds us climbing the hills on foot, to stretch our cramped limbs and ease the horses, as in old times the English tourists climbed the St. Gothard on the way to Italy. We are chilled, and racked by the jar of the road, and glad of even strenuous freedom. Presently we get on again, and ride down the far slope. It is the camel-boat of the steppe, this tarantass.

A solitary gnarled tree shows in the waste of snow--the one seed that lived, on the barren waste, of all that the Siberian winds had brought. An eagle is watching from its upper branches. Further on are higher hills, with trees growing on their northern declivities alone. No foliage can stand the sun, which steals the moisture and bakes the rocks on the southern slopes. As we pass one of these isolated groves, the bald trees are seen to be packed with old nests; for the birds from miles around come hither, as the only refuge for their eggs. Deer watch us, standing ten yards off; for these Mongols are poor hunters and their religion sanctifies life. A lama may not kill even a fly: it might be his own father, transmigrated into this form for insufficient piety. A big white hare starts through the trees, stops, and runs again. Thousands of little marmots scurry to their holes in the plain at the alarm of the tinkling bells. A kite soars with a marmot writhing in his claws. Big gray jack-rabbits bound along the road ahead. A troop of partridges let us pass their wallowed holes six feet away. They peer up, their heads protruding from the snow, their yellow aprons glistening like shields, tame as guinea-fowl. At length we drive into Zoulzacha village.

One becomes after a time somewhat of an adept regarding quarters. To-night the village gives a chance. The most promising exterior is selected, and driving up, we prepare to enter. Cold and cumbersomely muffled, you worm under the felt hut-flap, and see through the pungent smoke of the brazier a dim figure seated to the left of a veiled altar. Bowed over a red-beaded rosary, he is chanting in a low voice, a weird oft-repeated phrase. He ceases as you struggle in, becomes silent, and looks up. “_Amur sein!_” he salutes in quiet greeting, and motions you to a place on the low sheepskin-covered couch, to the right of the altar, opposite him.

The open smile of his welcome shows white teeth hardened by the tough biscuit of his daily diet. You note next, with the pleasure born of seeing anything good of its kind, the light color and unwrinkled features of this young man of twenty-five. The gaze of his brown eyes is direct and frank. He is clean-shaven, his hair is close-cropped, and he has the appearance of a well-groomed horse. In contrast with the smoke-blackened, hardship-wrinkled faces of the older Mongols, his is as a drink from a clear mountain spring after stale drafts from a long-carried canteen. His color is that of an athlete trained under the suns of the running-track. His features are defined, the nose not so flat, the eyes larger than the usual Mongol type. His expression is earnest and sincere as he now stands up in his robe of rich orange, trimmed and girdled with red.

He welcomes the guests without question,--it is the rule of Mongol hospitality, but you feel for the first time what an intrusion it is for your great Russian tarantass-driver to shoulder his ponderous way into the home of a stranger, loaded with your bearskin rugs and rifles and bags of bread, and to pile them loutishly on the native’s couch. At the other huts wherein you have lodged, this sentiment has not come so strongly. Poor places they were: the hardship-lined faces; the soiled and ragged robes of the women, the threadbareness of the heaped-up sheepskins on the couch, all these revealed that your two-headed eagle of silver was needed, and your coming a windfall. But here are no sheep fenced in, making one feel that standards are superfluous. The fuel is put away in a basket, the bright fire-irons are ranged in a row. The couch of polished wood is orderly, and the skin-rugs on it are folded in their places. The little chests of drawers are brightly polished, and the yellow cap, with its lining of fox-fur, on one of them is new and clean.

But most of all, in the proprietor himself is there an air of freshness and cleanliness, of youth and vigor, and of self-confidence. When you burst into a place like this, covered with snow and muffled up in furs, disturbing the master of the house at his prayers; when your driver lays the uninvited mattress down in the warmest place, a man cannot but feel like a thrice-dyed barbarian bounder, even if the home be a fifteen-foot felt hut open at the top, and situated on the borders of the Gobi Desert. So feeling, the first impulse is to let the host know that you are not quite, of intent, what you are by accident,--a big hulking foreign savage. So you hastily think over what you can give to put yourself less at a disadvantage. The prized reserve of milk-chocolate comes to mind. “Will the host have some?” you ask.

“_Da blagodariou!_” he answers in Russian, to your surprise.

With mixed gladness at having made good thus far in any event, and regret at the diminished store of this commodity, you take a little spoonful of the snuff which the host is now offering in a beautiful porcelain bottle, patterned in flowers. Then you come back with a cigarette. Most of these people know what cigarettes are, though some smoke them with their noses.

“No, thanks!” and he points to his closely-cropped head.

Alexsimevich, who has followed into the hut, explains: “You speak to a priest, he does not smoke.”

A screen hangs before the altar opposite the door. You look hesitatingly at it. Without demur, the lama, at the visible interest, draws back the veil. There, in painted grotesqueness, is Janesron, the red god of Thunder, and bearer of the lightning sword. He glares down with his three eyes upon the sunken orbits of a sheep’s head, laid out as an offering. Black Gumbo, the six-armed good spirit, is also there, and both are surrounded by attendant demons. All are pictured artistically, the minute detail of Tibetan workmanship showing in their squat bodies. The polished wood of the frames is as finely wrought as a Japanese sword-hilt.

On the box-top, beneath the gods, are set out in neat array the best of Mongol dainties. These are disposed in little polished brazen cups shaped like wine-glasses. There are raisins and dried plums, caravan-carried from the far-off Middle Kingdom, and lumps of sugar brought down from Russia in some trader’s pack. Millet fills one cup, water another; each symbolizing some ancient seizin. A wick, sunk in oil, flares in the centre, and casts a flickering, uncanny light upon the deities. Spread on a low seat, six inches above the felt rug on the floor, are rows after rows of _boba_, the gray Mongol biscuits, in shape like the thick soles of a sandal. As a centre-piece between the stacked loaves rests the brown roasted sheep’s head. It is the feast of the New Year that this unusual volume of offerings betokens. The old year of the Horse passes with the rise of to-night’s new moon. The leap-year--that of the Ram--will then begin. All the families in the _eimucks_ of Mongolia will feast on the grosser part of the offering which now lies in its ranked regularity undisturbed. For the present the priest takes light refreshments while waiting for his midnight rite.

“Will you have some of the tea that has been brewed for you by the old mother while you were looking at the altar?” asks Alexsimevich.

It has been made, not from the loosely-packed leaves, but from the hard tea-bricks. A chunk of this has been cast into the great iron bowl over the brazier when the fagot-fed fire has melted the ice and has brought the water to a boil.

Solemnly you are presented a wooden bowl of tea, which you receive in both hands, and as solemnly sip. The evening meal is cooked and eaten, your sugar reciprocating the lama’s tea.

As the evening wears on, amid the smoke of cigarettes and brass-bowled pipes, the lama brings out quaint paper slips of Buddhist prayers.

“You are interested?” He will write for you a charm. “_O mani padmihom_,” he tells you. “The Buddhist prayer.”

“Oh, thou jewel in the lotus-flower, hail!” says the interpreter.

It is mighty, this ancient Buddhist prayer, which is murmured by so many millions from Japan to Persia, from Malay to Siberia. It is symbolic, esoterically, of much. The jewel is the soul, the lotus is Buddha, the prayer, a wish that the spirit be in them which was in _Saka-muni_, their Lord. On endless rosaries this prayer is told. It is on the lips of priests and women, it is carved around the stones which travelers throw upon the _obos_, the “high-places” of Old-Testament record. It is murmured by the pilgrims as they prostrate themselves. The disciplined body, the praying tongue, and the mind intent on sacred things, all incline the soul to the acquirement of merit.

The lama draws now with his quick hand, trained to the Tibetan script of the Urga monastery-school, sketches of his temple, _Zoulzacha Soumé_, of his people’s summer tent of cloth, and winter hut of felt. He writes out the Mongol numerals, and explains the cycles of years, in answer to questions regarding the New-Year festival. He describes the puzzling element-and-animal system, by which the _chére mari_, or earth horse, is 1907, the _chére khoni_, or earth ram, is 1908, and so on through a sixty-year epoch.

He quotes Mongol proverbs come down from old priests and rulers: “One may buy slaves, but not brothers,” and, in the spirit of Macchiavelli, “You can govern a State by truth as well as you can catch a hare with an ox-cart.”

Now it is nearing moonrise. From his rolled purse the priest draws a small slip of paper ruled into a half-inch checker pattern, in every square of which there is a symbolic group of letters. The lama consults this. Then he brings from the chest beneath the altar a long narrow box in which are strips of faded paper thick as parchment. On these in red and black are traced quaint characters, written, as is our script, from left to right. The priest selects a dozen of his long sheets and puts them carefully on his couch. He touches the box to his forehead and restores it to its place. Then he turns and speaks to the interpreter.

“The lama must make ready for the night of the New Year,” you are told; and as you look, off comes the red sash and yellow robe. The young priest stands up in his vivid blue jacket and walks to the entrance of the _gir_. From a cupboard he takes a towel, and

from the fireplace, ashes. Pouring warm tea into a wooden bowl, he scrubs hands and face with the vigor of an athlete after a run. Then back to the cupboard he goes, and off comes the blue jacket for a clean new silken one. A rich yellow robe is donned. A bright silver knife is slung upon a new red sash which girdles his waist; and smart and erect as an officer of the Guards, the lama steps over, prostrates himself before his deities, then goes out into the night to his temple service.

“Creeds are many, but God is one,” murmurs Alexsimevich.

It is regrettable that the rule of lama celibacy prevents the arrangement of the usual kidnapping marriage-ceremony between this young priest of Zoulzacha, and Amagallan (blissfulness), the belle of the Odjick encampment. It is early in the first moon, Sara, of the year of the Ram, and holiday still reigns in Mongolia. Doubtless she, too, is a sooty Cinderella at other times; but to-day she is a reigning princess, dressed in the best that a father, owner of a hundred sheep, can furnish. A bright new blue coat, lined with fine white lamb’s-wool, is belted around her rather ample waist with a red sash. Her boots are of evident newness. But the triumph, the chef d'œuvre, is her pointed red hat made of the brightest Chinese silk. It is topped with a gold and black knot and is garnished with gold braid. The flaps, turned up at the sides and the back, are of a long silky dark-gray fur. A broad red ribbon fastened behind is brought forward and rests on her breast. She has a feminine eye to its brilliant contrast against the blue dress. Two long tassels of pearls, set in coral-studded silver earrings, frame a rosy, laughing face; for Amagallan is exhilarated with the consciousness of being very well-dressed.

The presence of two young herdsmen in dark red and blue, and one lama of the first degree,--and consequently not estopped from the race, like a full-fledged priest,--bears testimony to the effectiveness of the costume and the girl. The wiles with which she distributes a smile to one, a dried Chinese plum to another, and a mild frown to a third, reveal even more the universal woman. Amagallan is not at all averse to adding to her string three masculine Russians. There are only two foreign nations in Mongolia, Chinese and Russians. Into the latter class come all stray visitants--Americans, Buriats, and Troitzkosavsk teamsters. The girl stands up now and greets this American with a frank hand-shake. She invites him to sit down with the rest. Since there is scriptural permission to eat meat offered to idols, the fact that the evening’s feast has stood at the feet of Buddha need not deter one from partaking of the little dumplings, gray cheese, and dried fruits. Amagallan hands them out on one of those sole-shaped biscuits, which serve as plates until one has eaten what is on them, after which they go down themselves. A fat sheep’s-tail is sliced for your benefit, while a coarse lump of dusky-looking sugar is an ultimate delicacy, eaten as candy. Muddy brick tea follows, of course. The Mongol bread is good, but it takes resolution to do one’s duty by the gray cheese, the resin-like desiccated milk, and the sheep-fat just seethed.

A chatter of conversation goes on, the neighbors drift in and out, and those of our _gir_, as the evening wears on, make excursions to the other huts and exhibit and drink more muddy tea for politeness’ sake. The hostess in each tent shakes your hand before feeding you. The formality makes you temporarily one of the tribe and family, to be treated with courtesy and hospitality. Thus you are taken into the social life of a simple affectionate people.

We meet in one hut a traveling friar who has tramped sturdily from Tibet, pack on back and prayer-beads on arm, begging, praying, selling relics claiming to cure rheumatism, and the eye-diseases which the smoky huts induce. He carries on a pole an image of Gumbo and others of the _dokchits_, together with a hodge-podge collection of rosaries, strips of silk, bells, beads, pipe-picks, etc. These are jingled during parts of his prayer, where it is necessary to keep the god attentive.

[Illustration: A MONGOL “BLACK MAN”]

In one hut they are playing the age-old game of _tawarya_. A bag is produced containing hundreds of sheep’s-knuckles, colored blue. Everybody gets a handful. Then a girl holds out her fistful of them, and each man guesses the number. There is a rapid fire of shouted numerals,--“_niger, hayur, urbu, durbu!_” The one who guesses correctly gets the handful of knuckles. This person next holds out his fistful, and so it goes. It is an uproarious sport, interspersed with quite unnecessary grabbings of disputed handfuls,--part of the game that Amagallan is playing, even if not germane to _tawarya_.

Finally through the darkness you make your way back to the _gir_ in which you are billeted. The wreathing smoke from its dome is illuminated to-night by the beams from the fire below. It rises in dimly bright convolutions, beautiful in its small way as the great Northern Lights. You spread your felt on the floor of the tent and roll up in your rugs. The teamster needs a timepiece to regulate his hour of harnessing, for you must start at daybreak. Leave your watch for him on the altar of the _dokchits_. It will be safe in this hut by the desert of Gobi, among the remnant of the Golden Horde.

* * * * *

The days' marches have taken us well up among the ridges of the Kentei Mountains. To the eastward is the peak which, despite the claims of Urga's Holy Mountain and of a site near Tibet, has the best authority for being the burying-place of Genghis Khan.

In 1227 the great conqueror died. The confused records tell of his body's being taken northward to a mountain which was the heart of his empire, from whose slopes sprang the sources of the three great Mongol rivers,--the Tola, the Onon, and the Kerulon. Beside its sacred lake the Manchu Amban of Urga sacrifices annually to the Nature-spirits. It is both a survival and a memorial to the bloody sacrifice of every living being on the road to the grave,--a tribute which tradition says the guards of Genghis Khan's funeral cortège offered to their departed chief.

Huts are far apart in these highlands now, and the whistling winds pierce the very marrow. The tired horses can hardly crawl forward on the doubtful trail. Far up in the heights, beside an old caravan-route, superseded by a newly-cut artery of travel, we come very late upon an ancient wooden shrine.

The worshipers have gone. They lived their time in a village near by, but with the exhaustion of pasturage for the flocks, under nomad necessity they moved. A new camel-road was tramped out by drivers, who must find shelter amid habitations. So in the shrine, long unpainted, the smiling Buddha presides now over his famished altar.

Very, very old, very, very poor, is Archir the warden, who welcomes you. For forty years he has watched in his _gir_ by the dragon-gargoyled gate. The spear with which he stood to his post of old is blackened, and its red tassel is dulled and faded. A tattered fringe is along the edge of the felt door to his _yurta_, and holes are under its walls close to the ground. His pile of wood is pitifully small, and few are his sandal-sole biscuits. His _shuba_, sheepskin-lined, is blackened with the soot of years.

Archir refuses courteously what he knows is a rare foreign delicacy, a Russian cigarette. "A lama," he says, "may not smoke." But his own hospitality is of the thoughtful kind which comes from the heart. He hands you a sheepskin softened by long massaging between his trembling old hands, that his own covering, not your coat, be burned by the sparks from the brazier. He notices that your tea-bowl is awkwardly held, and he brings a little table to put before you. He sees your driver fumbling for a match to light his pipe, and reaches him a coal with the fire-tongs. He clears his couch that you may sit in comfort. He offers you the first use of his fire for cooking.

In the old days many came to pray to the smiling Buddha. The drivers of the tea-caravans from far-off China left their offerings of fruit and silk scarves. The herdsmen whose lambs had lived well through a bitter winter gave sheep fat of tail to the two yellow-robed priests who chanted and clashed the cymbals through the long days and into the nights. The little boys dedicated to the gods, shaven-headed, rosy-faced, crooned their lessons in the Tibetan tongue, sitting on the floor of the big blue school-gir beside the shrine. Every day pilgrims on their way to Urga stopped to pray in the _soumé_, and filled the tent of the young guardian with eatings of noodle-soup and drinkings of tea, with gossip and with song.

But all is changed now in his little hut. The rule of non-marriage he keeps in the spirit, where so many lamas observe it only in the morganatic letter. This has left him alone in his old age, and pitifully solitary now that even the dwindling camel-trains, of whose tea-traffic the Manchurian Railway has robbed them, pass by no more. The priest is unfed even by pilgrims. These have gone with the rest to the routes of a better prosperity.

Archir has seethed his evening meal of sheep-meat and flat pieces of dough. He has let the fire die down to embers, and has pulled the covering over the round hole. The freezing winds very soon make his hut so cold that one feels like a thin shaking uncovered creature even beneath the heaped furs. One's ungloved hands grow numb as he lies by the brazier.

In the morning we too depart, and like the Roman legionary beside the Vesuvian gate of Pompeii, the old priest waits, alone, unquestioning, uncomplaining, till a greater God than he of the _soumé_ shall send the summons of relief.

* * * * *

The mountain-ranges, one after another, stretch their towering barriers across the path. They trend northeast and southwest, as in Siberia. First comes the Sharan Daba, the white range, whose pass leads down to the Iro River, rich in alluvial gold. The streams flow westward into the Cellinga, whose waters empty into Lake Baikal, and thence by the Angara River, into the far-off Arctic Ocean.

Ridge follows ridge now, and valley follows valley,--narrow cuts, with shallow streams, and huts clustered upon their sides. Out from the almost deserted borderland, the Mongol encampments are not unfrequently pitched where there is water for the flocks. If any wood be near by, it is well, since then the dried dung can be reserved for the smokeless evening fire when the top hole is closed.

When the steep mountain climb has been passed, it is as if a gateway had been opened through the constricting ridges. The broad valley of the Haragol stretches out. Down, down, we go, onto a plain, in the centre of which we come to an enclosure with a high mud wall and a peaked gateway, gaudily decked with red banners and vivid placards. Outside the mud walls of the compound, far and wide, are checker-board squares with irrigation ditches between. Huge stacks of hay and straw are piled up near the gate, the wonder and envy of the nomads, who never have more than the scantiest store. Within are booths facing the courtyard. A little temple occupies one corner. Two-wheeled carts are drawn up along the wall. Troughs and picket-poles are ranged in line, ready for the caravans.

Now, around the tarantass, there gather from their threshing the dwellers of the compound,--coolies from the far-off Pink Kingdom, with puffy blue trousers and tight-buttoned jackets, flail in hand and metal pipe in mouth. They stare stolidly without comment at the frost-covered horses, the robes, and the bearded strangers. Expressionless they stand watching every movement. Alexsimevich asks a question; no one answers. We sit for a moment mutually expectant. Not one of the Chinese stirs or speaks.

Then André swings down and leads the team through the gateway into the compound. Alexsimevich leads the search for shelter. We cross the courtyard to the building which serves for the lodging of travelers. Its walls are of mud, and a big adobe chimney projects up one side. Beneath low eaves a small window with white paper panes blinks like the sightless eyes of a blind man. We stoop, pushing open the crudely pivoted door, enter the smoky chamber, and the door swings back behind.

We are standing in what seems an unreal world--a stage-scene or a cavern from the Arabian Nights. In front and on each side close in dark windowless walls. Behind comes a feeble light from the little paper-paned window. In the dimness, a flickering fire throws fitful gleams on dusky figures, idols, and wearing-gear hung on pegs driven into the wall.

As your eyes become accustomed to the gloom, the details take shape. A clay stove is to the left. Fagots are heaped beside it, copper kettles rest upon its top, pigtailed figures are crouching around. In front, a platform, raised four feet above the clay floor, occupies the whole width of the room and extends back into the darkness. A group of men are seated, cross-legged, around a little brazier, smoking. Others are lying rolled in blankets.

With our luggage André staggers in. No one stirs. Some of the group around the stove turn their heads to look, but that is all. André heaps the food-bag and blankets in a vacant spot on the _kang_. We make room on the stove for our pots to boil the water for tea. On this self-elbowed place amid the rest we sit cross-legged, propped against the clay wall. The smoke from the oven, led under the _kang_, warms it so that the outer coat can come off. A little tabouret some six inches high stands in a corner, and serves as a table for the repast.

The shelter is far better, as comforts go, than any of the Mongol tents. The icy wind that sweeps the latter is barred off. There is a stove to replace the nomad's brazier; a warm _kang_ instead of the floor to rest upon. But how different is the spirit of the hosts! There are no frank hand-clasps here, no interested gossip and inquiries of the adventures by the way. No generous bringing out of fat sheep's-tails and snuff-bottles for the guests' delectation. You cannot but have the feeling that these people are as indifferent to your existence as they are to the pariah dog that howls outside the walls. They are exclusive, non-welcoming,--these Chinese. They are strangers to the land, self-sufficing in their toilsomely cultivated rye- and wheat-fields, an isolated, womanless, working settlement.

Despite the better quarters and comfort which these inns afford, one prefers to go to a Mongol tent and be among men more human, if less civilized. When the bread is thawed and the tea is boiled, we eat, pay the Chinaman who gave the wood, and with a sense of relief go out again to the tarantass and the road.

For versts now the way is along the alluvial plain, seamed with irrigation-ditches and dominated by several of these walled Chinese factories. As the sun goes down, however, there appears a solitary building, and André gives a glad shout, seeing that it is built of wood and has windows and big centre chimney. "_Russky dom!_" he cries.

A low mud wall surrounds the enclosure. Inside some quilts are hung in the air, that the cold may kill the vermin. A big black dog comes up, but unlike the scavenger beasts of the Mongol encampments, it signals welcome with friendly tail-waggings and

good-natured barks, approaching at once as if accustomed to kindly treatment.

The quilted door of the house opens. A booted figure appears with the familiar red blouse, and the Russian greeting hails you, "_Zdravstvouitie!_"

"An Orthodox Buriat," says Alexsimevich.

We mount his wooden steps, shake his hand, and enter the big warm room.

It is as if one were back in Siberia. The Buriat's Siberian wife, in shawl and kerchief, is busy at the whitewashed oven. Brilliantly-colored comic prints detail the misadventures of the young recruit, with doggerel ballad rhymes beneath. Chickens peck beneath the stove, the samovar hums on the table, and figures sipping tea are grouped around it on the benches, or are lying on the floor enjoying the genial warmth.

"Hail, Alexsimevich!" comes a voice; and a tall bearded Siberian, dressed in a Mongol robe, rises.

"Aha, Vladimir Vassilivich!" answers our interpreter. "Good-day!"

A volley of questions at once overwhelms him. The party has been long away from Kiahta, and we have the latest news.

"A Kiahta merchant, my friend, and his son," Alexsimevich explains.

Overcoats are being doffed, mufflers unwound, and boots kicked off. The babble of talk continues. A place is made for us at the table, and glasses of tea, with immense slices of cheese and ham, are placed before us. When more tea and cigarettes have completed the repast, Alexsimevich paces up and down, relating with dramatic gestures the latest gossip from Troitzkosavsk.

In the midst of his narrative, which all are following with great interest, there comes an incident of heightened vividness.

"Sh--sh!" a warning signal sounds. One of the auditors points to a shape rolled in blankets, and lying on the bench.

"_Gaspaja_" (a lady), they say.

Alexsimevich completes his tale in a lower tone and with more artistic circumlocution.

But it is the other side's turn to tell a tale, for why, in the ferocious cold of midwinter, with--save for this one Buriat's house--the Mongol huts only for nightly shelter, why does a lady come down here?

The merchant explains: "She has twisted her knee-joint, and in Irkutsk, in Tomsk even, the Christian doctors cannot heal her. A lama tells us that warm sulphur-water will soften the sinews, and the bone can be brought back into place. We go to the warm springs of the Holy River. I have been there in old times, and I know the way."

With pathetic eagerness the party has gone to do the lama's bidding, and bathe in the Mongol Jordan. Evening comes. The lady's bench is pulled over close to the oven. The merchant and his son lie down beside it on the floor. Servants and drivers roll up at their feet, and all sleep, in amity.

It takes resolution to awake at daybreak and leave the luxury of this shelter. But when horses are harnessed, riders must ride. The rising sun comes up over the white plain. The Buriat waves "good-bye" from his doorstep; the dog barks in farewell, and we lumber on southward.

A sugar-loaf hill marks the end of the valley. We turn up now into the mountains, the driver somewhat in doubt as to the way. A boy of about fifteen years, a yellow-robed lama novice, rides by. Alexsimevich hails him to ask the road to Urga. A complicated explanation follows, hardly understood.

"I show you," says the boy.

For a dozen versts he rides along on his pony beside us, chattering and laughing. When, after a devious trail, the pass is in sight, he starts off, and will not, at first, accept any present for his trouble.

Valley follows valley now, the trail fairly well defined. Mongol huts give a chance for rest and for cooking. A welcome is bidden us in each, the nearest water is shown, and invitations to come back are freely extended.

There is now one last range to cross, the Tologoytou, highest and steepest of all. Even the mounted Mongols, who have caught up with our toiling tarantass, swing off and climb afoot. Trees are on either hand, and the white wall-like face of the barrier passed in the morning seems a bare verst away. There comes a whole slope of boulders and rocks, jagged and broken, like the moraine of a glacier. And then, at long last, we reach the high-heaped Borisan at the summit, with its fluttering prayer-flags. The foremost Mongol throws on a rock, leaps upon his pony, and rides twice around the mound.

"_Argila! argila!_" (bridles free! bridles free!) he cries, and trots down behind the crest.

We, too, throw on a stone, and take the steep descent.

Beyond the low rolling ridges below is the white of the Holy Mountain, topped with green foliage. Here one may not kill the thronging hare and deer and pheasants. As we gallop down, the _obos_, the white memorial monuments, take shape from the snow. In the dark-gray dimness of the city beyond, green and gold roofs become distinct, lighted by the last glow of the sinking sun. Huts cluster close now along the road, and the shadows of innumerable dogs pass and mingle and pass again, where the gray mud walls and houses begin to be continuous. In the dim twilight the tarantass thunders into the great wide way which ends in the main street of Urga.

Two hundred feet broad is this street. Mud walls twenty feet high flank it. The gates to the enclosures are closed. The fast-fading light discloses hardly any passers-by. Save for a distant tom-tom there is deep silence brooding over the city. A great empty square is entered, where a few figures are passing in the distance. We approach one of these, who upon our question lurches up to the tarantass. He is a Russian clad in Mongol _shuba_, rather the worse for liquor.

"I will show you," he says amiably.

Affectionately leading the horses, he reels down one dark alley, then down the next, until we come to a second broad street and to an enclosure with a lantern-lighted gate. A cry brings at length a stir within. The gate swings open.

"The _Varlakoff_ house!" says the guide thickly.

The tarantass is led in, and we stumble through the darkness into a Russian home of some pretensions. In the main room is a lamp and a table covered with a red cloth. A glass of tea is available and is quickly swallowed. Then, tired out, we roll up in our blankets, on the floor, and drop off to our first night's sleep in Urga, the Holy City of Mongolia.

VI

THE CITY OF THE REBORN GOD

The murmur of many voices pierces the blanket over your head. Sleepy-eyed in the warmth, you peer out from the chrysalis of coverings to watch the people moving about. Alexsimevich has extricated himself from the mound which he constructs nightly on the floor, out of luggage-bags, felt mats, rugs, and overcoats. Under all the heaped wrappings that he uses in the icy Mongol tents, he has camped and slept close up against the white wall of the oven. Truly the Siberian is brother to the salamander. He pulls on now his big felt boots and runs a pocket-comb through his beard.

The wife of our host, come to the door for a survey, notes progress and returns to the female region. The Hazan Varlakoff, gray-bloused and wearing deerskin boots, enters next. He lights his first cigarette; his wife with the bowl of sugar and the plate of bread follows. She has gotten up earlier than her husband, so she is several cigarettes ahead, but he is cutting down the lead.

Perhaps one had better get up one's self. It is an easy operation here. "Getting up" consists in emerging from the rolled blankets and stretching. "Dressing" means pulling on boots. One can wash over in the corner, where the brass can lets out a trickling stream of cold water when the needle-valve underneath is pushed up.

The samovar hums on the red cotton cloth of the table. Varlakoff moves along to make room. From the little pot of infused tea your glass is partly filled; then you place it under the spigot for hot water, and the beverage is ready for sipping. No lemons are here, as in Russia. In a few Chinese shops one can buy spherical citrons, but they are like unripe oranges, and are a luxury as great as pineapples in old New York.

A wool-buyer from Kiahta reaches for the bowl of broken loaf-sugar, and holds it for you to choose the piece whose size pleases best. The housewife comes from the kitchen over by her oven-door, bringing some crestfallen cake which she has made in your honor.

"_Kuchete! kuchete!_" she commands, arms akimbo, puffing contentedly on her cigarette.

We revel in the luxuries of Varlakoff's room; warmth such that we may take off the cumbersome outer coats; chairs to sit upon, instead of crouching cross-legged; hot samovar-made drinks, and a chance to wash in water. The latter is a privilege which can be appreciated only after a period of ablutions in lukewarm tea. We stretch out and bask and sip, and whiff _papirosi_ in epicurean idleness.

As we luxuriate, one by one the neighbors of the Russian colony come in, to hear the news of Kiahta from Alexsimevich. The expedition has become part of the gossip-transportation system. Half the population of Kiahta must have sent messages here,--half the Russian traders in Urga have come to receive them. First, there is the general news dispensed into the expectant ears of the group at Varlakoff's. Alexsimevich is for an hour the cynosure. Questions and answers flash back and forth, going off sometimes explosively like fireworks. Then follow the special events and the individual messages. At last these are all detailed. Now come invitations from various men to visit their houses "Will the _gaspadine_ come?"--"The _gaspadine_ must see the city."--"_Da! da!_" echoes the group.

Varlakoff goes out for his stick and overcoat. The wool-merchant gets into his fleece-lined _shuba_. He achieves the feat by the usual Siberian method. Putting the garment over his head, he pushes his arms through the sleeves, and gradually struggles and writhes up into it as one gets into a wet bathing-suit. Alexsimevich finishes his fourth glass of tea, lights one of the _Hazan's_ cigarettes, and worms his way also into his deerskin greatcoat. Then out we go into the bright sunlight and the snow-covered streets.

[Illustration: TEMPLE OF GIGIN, URGA]

The houses of the Russian quarter of Urga were only glimpsed in the dusk of last night. We have daylight upon them now. Squat whitewashed buildings they are, with neatly paned windows and big square chimneys. Across the mounds and hillocks of a broad street is the one-storied Russian Club, where one may drink vodka, play billiards or cards, and while away the winter evenings. Further on is a row of shops. The bearded owners stand behind their counters, dressed in belted Mongol _shubas_ and Russian fur caps. The doors to all the shops are open, that the Mongols, perplexed with knobs, may not take their trade elsewhere. Enameled kettles are hanging in festoons down the walls. The shelves are crowded with bolts of vivid-colored cotton cloths to be sewed into _shubas_ by the Mongols who ride in to buy. There are big cases of sweetmeats, Moscowski caramels, acceptable offerings to the grotesque _dokchits_ on the family shrines. Russian monopoly tobacco is there, in stamped paper packets for the delectation of Muscovites and Buriats who have the taste and the means, and villainous South-China tobacco and snuff for native purchasers. One can get vodka almost as bad as that of Siberia, and far cheaper, for it is compounded by a local distiller who rejoices in an excise-less market. Foreign brandies and wines fill big walls of shelves.

"_Zdravstvouitie!_" one of the merchants calls, hailing our party.

"It is Vassili Michaeloff, old friend of mine," says Alexsimevich. "Let us go in."

We enter and are led back into the private part of the house.

"_Chai!_" shouts the host to somebody behind the oven.

"_Haracho_," comes the answer.

We all sit down. If any purchasers drift into the shop, they can wait until we get through our visit, or they can go down the line. For wherever the Eagles are planted, the Russian joyfully drops his business to entertain a friend. At the call of "tea" the shovel goes into the ditch, the ledger onto the shelf, the pen into the potato. If "_chai_" interferes with business, cut out business. Nor does it matter in the least that we have just had breakfast; by the rule of etiquette we must be entertained. "Tea" consists first in a ceremoniously clinked toast drowned in vodka. Then appears the samovar in charge of the woman of the house, the glasses, and the sugar. Next follow the cigarettes. The talk is animated, for its local history absorbs each little world. The fact comes out that the cousin of Michaeloff has bought a new pair of horses for a hundred roubles. The price, the quality of the animals and of the man, all go into the crucible. Kiahta beer arrives as the conversation turns to the death of one Ivan Vladimiraef, which it is agreed was not

unnatural, since he had reached the age of ninety-odd years. Still the provisions come. The good wife brings in a heaping plate of lard-impregnated Hamburger steaks, called “cotlet,” which Alexsimevich attacks as if his last meal were half a day instead of half an hour distant. Other bottles accumulate to help out the dwindling flagon of vodka. We enter upon Château Yquem, Pomeranian, and Caucasian claret. Then cakes are set out, and more tea, and finally a quart bottle of champagne.

Alexsimevich stands to his guns like the 38th Siberians at Tien-tsin. But it is hard for any one of less rigorous training in this sort of thing to hold even the straggler’s pace at nine o’clock in the morning. Mentally we hoist the flag upside down, and wink at Alexsimevich as the outward and visible sign of the inward and spirituous distress. He takes the rest of the champagne in a last gulp, and with a series of thanks we gain the entrance to the shop, where two Mongols and a Buriat are waiting patiently, looking vacantly around at the crockery.

We are shown ceremoniously to the door, shake hands, remark about the weather, give our compliments to the wife, and depart. When at the corner, we glance back. Vassili Michaeloff is still standing on the threshold; his three customers too are looking out leisurely at the people passing.

“We have thrown his business out of gear,” we remark to Alexsimevich.

He seems surprised.

“There is plenty of time. Why should they mind waiting? _Nietchevo._”

Another host is overjoyed to see us, for an engineering problem of great perplexity is, he tells us in due course, harassing his mind. No one in Urga can help him out, but perhaps we will.

“The Chinese governor, the _Zinzin_, wants to make an automobile line from Kalgan,” the host announces. “I saw an iron bridge once, so I agreed to build him one over the Lara River. Have you ever seen an iron bridge? How shall I do it?”

You allow that you have seen an iron bridge,--that you have even gone across one. You suggest that much depends on the river. “How wide is it, for instance?”

“I have not picked out the place for the bridge yet,” answers the host; “but the river is somewhere between sixty and three hundred feet wide. Have some vodka?”

“And how deep is the water?” you ask.

“Well,”--after much thought,--“it is deep in the middle and shallow at the edges. Have a cigarette! Have some tea! If we build this bridge, the _Zinzin_ will give us a decoration. How much will the bridge cost?”

“That depends upon what sort of bridge you build, and how long it is, and how much material you use!”

Alexsimevich comes in.

“You see, the more iron you use, the more the bridge costs,” he observes.

“_Navierno! navierno!_ you speak sagely, Alexsimevich. That is what I told the _Zinzin_.”

“It must have piers and abutments,” you venture.

“But the _Zinzin_ does not like piers, because the water was not made to put such things into. Yet I said with you, one must always have piers. Here is brandy. Take a few sardines!”

The problem certainly needs something special for its elucidation. You ponder, and Alexsimevich and the host breathlessly watch the hatching of your official pronunciamento.

At last you deliver yourself.

“Find out how wide and deep the river is. Then write to a steel-manufacturing company, to quote prices. They will send a blue-print of an automobile bridge of the specified length, together with the weight of the steel. You can buy pieces to build it at so many kopecks a pound, just like butter.”

“Ah, my friend, you do not know how great a service you have rendered! What a providence is your coming! Pray, have some cognac! Will they send me a picture with piers,--a picture that I can show the _Zinzin_?”

“Yes,--yes, indeed.”

“I go to-morrow to tell him of this.”

We are once more in the street and the banded escort is turning into still another Russian’s house. Their idea of sightseeing is apparently to take tea with every Russian in the place. A mild desire is registered to come in contact with some of the other people. The idea strikes them in the light of a strange new doctrine.

“You wish to see Mongols?” one asks. Though surprised, they acquiesce amiably. “To-day they have holiday; you are favored. Go see the doings and make me visit later,” says the disappointed third host.

Then the wool-merchant speaks.

“Near by is the great temple of Urga, which few have seen, for it is one of the most holy places of the Lama faith. It is the temple of Maidari, the Future God. If the _gaspadine_ wishes to see it, I, who have bought wool from the uncle of the keeper of the gate, can gain admittance.”

[Illustration: TEMPLE IN THE URGA LAMASERY]

For this we start. The Russian section, made up of shops with posters and signs in Slavonic letters, and homes with centre chimneys and little square panes of glass, is left behind. Through a long dark lane we come out into the main thoroughfare of Mongol Urga. The town is in festival for the New Moon. The streets are ablaze with color. Red posters are on every door and wall. The brilliant picture is framed by the snowy girding hills and the green trees of the Holy Mountain to the south. The tomb-like altars on the plain are dazzlingly white against the gray-plastered fronts of the houses behind. The gilded gargoyles of the temples flash in the sun. Down the main street, a hundred feet broad, go bevies of girls, their hair bedecked with the gaudiest ornaments of silver and pearl, their silken robes striped and banded in green alternating with yellow and blue and gold. Lamas stride here and there dressed in bright orange robes and hats, their silver knives hanging at their sides. Great shaggy-haired dromedaries swing past. Horsemen, robed in vivid scarlet and blue and magenta, dash at full gallop across the wide open _piazza_ in the centre of the town. A donkey-cart is driven slowly along, crowded with brightly-dressed girls. A squad of Chinese cavalry trot by in white jackets, red-lettered. Two of the Cossack garrison swagger past. A bearded Siberian trader strolls across, clothed in the dark Mongolian cloak which most have adopted, going toward the Russian quarter we have just left. A string of oxen plods by, drawing cartloads of wood.

Walking on, we come to a long line of kiosks which a continuous procession of pilgrims in holiday attire is entering. In each booth is a cask-shaped prayer-wheel, a magnified model of those which women carry, twirling them in their hands as they walk.

Along this main square of Urga, and girding her city stockade, are hundreds of these cylinders. All the day long, men and women are going in and out from one kiosk to another, turning. Some say that formerly one could enter a great Tibetan temple only after saying a prayer so long that even a Grand Lama’s memory could not carry it. So, for convenience, a cylinder with the written text was set up at the temple gate. By degrees it became the custom, without reading it, to rotate the petition for a blessing. Others say that the wheels are whirled in literal obedience to Buddha’s precept to “turn over and over his words.”

Alternating with the wheels are stone shrines graven with Tibetan characters, before which, on wooden couches, silken-dressed women are abasing themselves in abject worship. A long line of pilgrims is doing the circle of the city. They stand, then drop prostrate in the snow. Rising, they move conscientiously forward to where their heads touched, and again lie prone, making thus a penitential circuit of the stockade. Most are in deadly earnest. Some, hired for a proxy service, steal forward a few inches on each prostration.

Suddenly three distant guns boom out.

“_Scurry, scurry toda!_” says the wool-merchant. “Quick, this way. He is coming.”

You hurry forward to where a trail leads across the square. Afar off, in the direction of the Holy Mountain, is seen a band of galloping cavalry. The Mongols on horseback around you are drawing rein. The pilgrims are looking toward the approaching cavalcade. Brilliant red and yellow are the robes that flutter as the body-guard ride. Now a rumble of wheels is heard among the

clattering hoofs. Preceded by twenty horsemen, followed by twenty more, rolls down a Russian droshky, with a yellow-robed lama driving. Propped among the multicolored cushions sits a clean-shaven, silk-robed man, with puffy cheeks and tired eyes. The European watch which he carries hangs in anomalous awkwardness at the breast of his robe; his leg is propped on the front seat, as if he were lame. Most turn their backs to him in Oriental honoring; many prostrate themselves in the snow; every horseman in the square has dismounted.

“He drives from his palace beside the Holy Mountain to the temple on the hill beyond the city,” says the wool-merchant.

“But who is it?” we ask, as the last galloper rides by.

The Russian looks at us as an old Roman might, if in the Forum we had not recognized Cæsar.

“That! That’s Gigin, the Living God! That’s Buddha come back to earth,--Gigin!”

You stand a moment to take it all in. Then, despite your purpose of respect, a smile works to the front.

At once the wool-merchant laughs gleefully. “Ask Varlakoff about the Buddha,” he chuckles. “Varlakoff sold him his ponies for ten thousand roubles. My friend showed him a picture of the ponies, little horses, you know, and Gigin told him to get them. They had to send to an island of Europe, Scotland. But Gigin was very pleased. He said Varlakoff was the only man who had never lied to him.”

The expression of the wool-merchant was that worn according to tradition by the Roman augurs.

“When there is not a holiday, the people have the market here in this square,” the merchant continues. “I was here in the bazaar with a friend last week, and we heard a commotion over by that prayer-wheel. We went up, to find that two of the Buddha’s lamas were borrowing a fine horse, worth three hundred roubles, which belonged to a Mongol woman. It was all she had, she told us, and it was being taken to the Living God’s stables. The woman was in great distress.

“‘It is mine. I will appeal to the Consul,’ said my friend.

“The Gigin’s men could not take a Russian’s horse, so they had to give it up. The Mongol woman came and wept on him, she was so glad. She brought a gift to my friend. Generally the Gigin returns such borrowed booty when he has used it a while, but often not. Anything that is new, the God will buy. These pilgrims, you see, bring him offerings. Kalmuks come all the way from the Volga, Manchus make pilgrimages, Buriats come down from north of Baikal, and tribesmen from Tibet. He has half a million roubles a year from his priests, and he does not care for anybody.”

Becoming more and more steeped in celestial gossip, we go past the gray-plastered compounds piled high with wood and timber, a main export of Urga. Tall masts with logs suspended from them are the signs. We reach at last a big stockaded courtyard, the beginning of the monastery quarters.

“Come, look in here!” says the guide.

You peer through the gateway at six of the biggest bronze _burgoo_-kettles that ever existed outside an ogre’s kitchen. Each kettle can hold a couple of cows.

“It is to feed the monks,” says your companion.

The Mongols are going up to the vessels, with buckets suspended to the end of a milkmaid’s yoke. They dip up a load. The soup looks like gray tapioca pudding. What it is made of remains one of the secrets of the monastery, whose chef is stirring the mixture with an oar.

A big stockade, enclosing tents and peaked _soumé_, from which the sound of chattering is heard, appears ahead. As we approach, a whole hive of boys swarm out and scatter in all directions. Some are in red, some in yellow, some wear ordinary Mongol caps, some wear high, yellow sugar-loaf fools’-caps, which fall over on one side. These are the novices in training for the lama hierarchy.

The first-born of each family must by immemorial custom become a lama. In babyhood and boyhood one of these dedicated children is clad in yellow robes and is especially tended. “_Ubashi_,” he is called. When about ten years old the boy goes to school, at Urga. He becomes a _bandi_, or student of the prayers and of the Tibetan language. He runs about as those we have just seen, and at about twenty he becomes a _gitzul_, or first-degree lama. Now he shaves head and beard, and wears a brilliant yellow and

red robe. Next he takes the more advanced examination and catechism, and becomes a full priest, or _gilun_, forbidden to marry, to kill, or to work. He may continue his curriculum in one of the departments of the lamasery, studying divinity, medicine, or astrology.

In the divinity course a lama will memorize Tibetan prayers, and pore for years over the big holy books which lie within the chests of the lamasery chapels. He will repeat the creed over his beads, in rapt self-hypnotism, meditating in celestial holiness. He will pray down rain for the grass, and will exorcise glanders from the ponies.

A priest taking the medical course will gain a knowledge of the innumerable herbs that grow on the Tibetan mountains, many of which are of great value as drugs, and are known only to these monastic seekers. Massage, warm sulphur baths, and waters, are part of his pharmacopœia. Mixed with genuine instruction in anatomy and medicine, he will be taught the incantations that cast out _tchutgours_, or evil spirits, the words of power to be written on rice-paper and rolled into a pill for the patient to swallow. He will learn what devil is responsible for the disease which has brought low the lusty herdsman, and the right order of image to make for allaying the infernal anger. He will be taught when the fever crisis is at hand, so that the cymbal-clashers, the drum-beaters, and the prayer-wailers may assemble, and by these holy noises and a transcendental counter-excitement, lift the patient over the fever-point.

[Illustration: A PROSTRATING PILGRIMAGE]

If he elects astrology, he will be instructed in casting horoscopes of unfailing value, in reading the stars, predicting their future stations and the coming of eclipses. He will be prepared to declare the reasons for visitations of murrain and to track the trail of straying camels.

Divers are the paths of knowledge, but all may lead to the honor of Grand Lama, head of a monastery, or member of the college of _shabniars_, who form the Council of the Living God. And when the great reaper has called the high priest from his earthly glory, a whitened tomb will be raised to his memory just outside some town along the camel-trail, while his ashes will be moulded into briquettes and godly images, to rest before the gods in the shrine of some _soumé_.

We have arrived at the gateway to the great temple. The wool-merchant disappears inside to work his pull. A young lama comes out to the door, smiles at the foreigner, and then goes in again, and you tremble lest your advent is being announced to some other than the one man who can supposedly be “fixed.” This is the most important temple of Urga, forbidden to foreigners, and seen through good fortune by a few only of the old residents. But every gate they bar to hate will open wide to love--and a ten-rouble note. The merchant comes back.

“We can go in while the lamas pray,” he whispers.

The uncle appears, with an expectant look on his face, and motions us in through the darkness to the anteroom of the temple sanctuary.

From the chamber curtained off at one side comes a low swelling chant.

“Service begins, you may see it from here,” the lama says, just above his breath.

Your station is in darkness, but just the other side of the curtain are the lamas, and their apartment is lighted by windows. Two rows of benches extend the length of their chamber, leaving an aisle between them, reaching from the door to the altar. A score of priests in yellow robes, with red sashes slung tartan-fashion over a shoulder, are sitting on these seats facing each other. They are ranged evidently in the order of their ages. Two old _giluns_, fluent in the Tibetan litany, sit next the altar. Then come younger lamas, the _gitzul_, not yet full priests. Finally next to the door are _bandi_, ten or twelve years old, intense in youthful delight that their part in the ceremony is to pound as lustily as they can the big prayer-drums. The service begins with the chanting of a ritual in form not unlike the Slavonic litanies of Siberia. At appointed times it is necessary to call the god’s attention to the fact that something is going on in his honor. At once a most deafening clamor begins. The small boy with a drum is drowned out by his big brother, further up the line, who officiates upon a huge wooden cornet, and by his uncle with the conch-shell or the cymbals. The droning of prayers is like the buzz of hiving bees. There seem to be no responses, but all of them read together. Presently comes a sudden clamor, almost like a fire-alarm; then the crash and the droning suddenly cease.

“It is over!” says the guide.

The lamas file out by a further door, and we tiptoe in to inspect the holy of holies at the heart of the great lama sanctuary. In the dimness one sees first before him the table for offerings, on which are the two main sacerdotal instruments,--a silver bell and a silver handle like a carving-knife-rest,--and row after row of targets made of dough-paste, of brass cups filled with oil to serve the tapers, of millet, rice, currants. Behind this altar, towering far up into the hollow of the dome, is the bronze colossus of the smiling Buddha, Maidari, the Future God.

Fifty feet in height, the figure is, cross-legged, with open, painted eyes. From Buddha's hands hang long silken streamers. One of very fine quality is embroidered with the ten thousand gods.

"This," the priest whispers, "is a present from the Dalai Lama."

A great festival takes place in summer in honor of this god, who will rule a myriad years hence, when the race of giants descends to kill mankind and to people the earth with their own kindred. The Gigin's elephant is brought out, and he himself takes the lesser dignity of a carriage in deference to Maidari. Even the gods of the present must honor the gods of the future.

The Gigin's throne is to the left of the statue. It has triple silk cushions. Around are twelve colossi of Buddha, some ten feet in height, and entirely gilt save for the red lips and the eyes. The hands are held in differing positions, folded, outstretched, pointing. Here and there a silk scroll is hung.

The walls of the sanctuary are lined with shelves like a book-store, and these are loaded with statuettes of the ten thousand gods.

We tiptoe back the way we came, and are soon in the street of the monastery. The uncle has seen us safely away. We betake our route from the Mongol toward the Russian section.

"You saw the throne cushion of Dalai Lama?" the wool-merchant asks. "They have put it back now. Gigin kicked it out of the temple when Dalai Lama left. The Angleski drove Dalai Lama from Lhasa, and he came to Urga to visit Gigin, because here is the second great Buddhist holy place. Now Dalai Lama is very monkish, very austere, and always prays and fasts. But our Gigin"--here follows another expansive smile--"Gigin rode out with his Council, the _shabniars_, and took some of Pokrin's best champagne in the cart, for they would not have it in Lhasa. Dalai Lama was very stiff. Gigin asked him, 'Have a drink!' Dalai did not understand, for drink is forbidden. Then he asked him again, and Dalai Lama refused rebukingly. They came to Gigin's palace at the foot of the Holy Mountain, which is built like the Russian consulate. After the prostrations, Gigin said to Dalai that he had come far and few women were on the road and those mostly old and ugly. Dalai Lama refused that too. Cigarettes and snuff, and canned tomatoes he offered, but Dalai Lama refused them all. Then, in the Assembly of the Lamas, Dalai rebuked Gigin, and made him sit below his servants in penalty, for Dalai Lama is more of a god than Gigin. All the pilgrims came to offer gifts to Dalai Lama, and Gigin did not get his. For months Dalai Lama stayed here. Afterwards he went away to China. Gigin came to this temple then and kicked Dalai Lama's throne, throwing it down. He celebrated in the summer palace when Dalai Lama left, for he was very happy."

* * * * *

Mongol Urga is left behind, and we reënter the Russian town. A hail from one of the passers-by is not long delayed. "Will you have _chai_?" he questions. He is an alert-looking Russian, smartly clad in a _shuba_ of green leather trimmed with sable.

"Must we eat any more dinners to-day?" we inquire.

"Only tea," is the reply. It is not quite reassuring.

"That is Pokrin, the one that sells to the Gigin," the wool-merchant whispers. "Go with him: he can tell you some tales."

Obviously one must not miss the acquaintanceship of this modern Ganymede, cup-bearer of the many-bubbled French nectar and jugged ambrosia; so on we march to his compound.

Pokrin was on his way to a business appointment; but no rendezvous will interfere with prospective _chai_. He hangs his coat back on its peg, bids his wife start up the samovar, and produces the vodka-bottle. Yes, his family is very well, and he is very busy buying hides. We talk up and down and roundabout numberless themes, and at last venture: "The Gigin!"

"Ah, the Gigin was here to see me only a week ago."

We bow our recognition of the host's great importance, and he is started; soon he buckles down into the story.

“The Buddha came up in his carriage with his lamas riding beside him, and they tied their horses all around here in front. Then Gigin came in, walking softly because of his gout, and he said, ‘Let us drink together like friends, without quarreling.’

“I brought out the drinks, and we sat down,--Gigin and I with the lamas around us. Gigin likes best the strong drinks,--not vodka, but cognac and sweet champagne. Very many bottles we drank, Gigin and I. And at last I fell asleep. But Gigin drank still. Then he too fell asleep. In the morning the lamas carried him to his carriage, and back he drove to the palace, with the people lying down in the street as he passed. All the next day I had a very bad pain in my forehead, and it felt large.”

By non-Siberian standards Alexsimevich should be on the way to similar symptoms in the near future. For the purveyor to the Divinity has produced an assorted collection of his wares which are being sampled with due diligence. Cold meats and wheat-bread appear on the table with the samovar.

“We must eat, or he feels badly,” whispers Alexsimevich, as he makes a sandwich, an inch and a half through, which is about the depth of brandy in the Siberian highball.

Other neighbors drift in as the afternoon wears on. The talk turns to that greatest of local events, the Metropolitan Handicap of Mongolia, under the high patronage of the Living God. Things become decidedly stimulating, and the recitals lively. Everybody is living over the excitement, ejaculating and gesticulating. The child-quality in their minds keeps so vivid their impressions, that the scenes are projected almost as by a cinematograph.

From hundreds of miles around, the herdsmen have assembled. The plain before the city is a riot of color, as the horsemen ride here and there. In the centre of the field is the gay pavilion for the yellow-robed bishops and cardinals from distant lamaseries, guests of the great Gigin.

All through the morning, hundreds of riders and horses have been making for the starting-point, twenty _li_ (about seven miles) distant. The jockeys are the smallest boys available: young red-cheeked lamas, perched bareback on the shaggy racing-ponies. The monks, who are stewards of the course, have with much shouting finally, at the hour, lined them up in a long row, facing Urga. One thousand ponies have been reported as entering. It is a regiment of boys. A signal starts the whole cavalcade together. The thousand small jockeys shout at once. A thousand whips come down on flanks. Two thousand heels dig into the ponies’ withers. Over the irregular plain tear the racers, dodging around gullies, stumbling in marmot-holes, galloping helter-skelter amid furious yells. At length they come within sight of Urga. Crowds, mounted, have gone out to follow them in. The shouts redouble, the people become frantic; the riders yell at one another, and the horses are as wild as their masters.

Shabniars and cardinals get to their feet as the cavalcade appears. The Living God’s heavy eyes brighten up with interest. His chief soul-mate waves a jewelled hand and chatters excitedly with a lama of the guard. The foremost rider is close at hand now, the jockey, wriggling like an eel and almost on the neck of his pony, yelling and slashing. The field thunders behind. The leader nears the pavilion, his pony is on the fierce final spurt,--a last cut of the whip, and in triumph, amid the deafening roar of the populace, the winner passes the line. Many other riders come in at his heels, but most straggle off to either side of the course when they see that the finish is lost. The victor is caught up by the priests and is brought before Gigin, where he lies on his stomach in adoration. He receives a gift, and is pensioned for life. The horse’s owner receives a good price for the animal, which is added to the Gigin’s stable. The mule-cart of the Buddha is then brought up and he is loaded in. The yellow bishops mount their steeds, and back to his palace goes the Living God. Thus ends the great Urga race.

There are other athletic tournaments during the season; most important of these is the championship wrestling-bout, which every year decides whether laymen or clergy are the better sportsmen. The Gigin’s pavilion fronts a ring, with dressing-tents on either side. From one emerges a layman. He advances by huge jumps and prostrates himself before the deity. Next, palms on the ground, like a great frog, he leaps into the ring. The chosen lama executes the same pass from the other side. They meet, jumping like game-cocks, with quick breaks. At length the clergyman gets a leg. In an instant he heaves up on it, and over goes the black man,--out! The whole assembled populace raises a stupendous howl. Bout succeeds bout, with differing champions and varying issues. Partisanship is intense. The clergy usually win in these matches, and have long held the championship.

One guest tells to-night of the photographer who bribed a lama, and got the first photograph of Gigin. The tale runs that this man, a Russian, secured admission among a crowd of pilgrims, and snapped the god, unawares, among his entourage of priests. This photograph, enlarged and colored, is the one now hawked to the Mongols, and which they set up for worship among their other gods. The lama was beheaded, they say. That was several years ago, however: since then Gigin has been photographed at the

races and elsewhere.

At last we break away from the group and return to our lodgings at Varlakoff's.

[Illustration: A GRAND LAMA]

We are informed next day that among the invitations so lightly and uncomprehendingly accepted was one to take dinner with the mayor of the Russian settlement. We are expected therefore toward evening. So, late in the day, we gird on our greatcoat and move out heavily. Down the street we fare forth to the house of the host. A fine well-fed man is this mayor, with the cordial grip and the slow smile of good-fellowship. He wears a very long beard. He has taken a fancy to the embroidered green and pink Chinese ear-tabs as a substitute for the big fur cap of his own people. The ear-tabs are about as appropriate to his burgomaster build as baby-blue ribbon on the tail of a fighting bull-pup. Otherwise, deerskin boots and hunting-coat, he is the real Siberian. In the mayor's large sitting-room, along the wall against which the table stands, is a rank of bottles of divers heights and fatness, like recruits out for their drill. The samovar of shining brass leads the array. Four different-sized glasses stand at each plate, and the intervening area is covered with platters of sausages, cheese, bread, sprats of every conceivable variety, and a medley of cold _zakuska_ dishes.

The mayor reaches for the vodka.

"Please, none!" we blurt out.

The mayor looks hurt. Then an idea takes form in his head, and he shouts something to his Chinese boy, who promptly shuffles through the door into the street.

Out of the window we catch a glimpse of him turning into the establishment across the way, where Pokrin's clerk sells the wherewithal to make a Russian holiday. The Chinese boy emerges with a bottle, and trots back across the street with the curious gait made requisite by the unattached thick-soled slippers. He shuffles into the dining-room and makes space for one more bottle. Whiskey! The mayor has bethought himself of the English label, and has sent for it, on the theory that not to drink, like not to sleep, is unbelievable.

Evidently one must again sidestep, so _chai_ is besought and got down. Our virtue is rewarded, for the host smiles and is content.

"Poor Pokrin!" he says presently, reminded of the man by the beverage. "He made over a hundred thousand roubles from selling things to the Gigin. But now he can't think of any more things to sell. You saw the Gigin's new droshky? But that isn't like selling an elephant or an electric-light plant. Pokrin is down to pelicans and fountain-pens."

He shakes his head sympathetically, and reaches anew for the vodka-bottle. He goes on reminiscing, half-cynically, half-regretfully, of the past, while dinner to serve the appetite of a Cyclops keeps coming on.

In the midst of the repast cries arise outside. A Mongol with a flow of language is heard calling aloud for "_Bulun Darga!_" (fat policeman.)

"They are after me," says the mayor resignedly.

The Mongol comes hurtling in, pushing past the Chinese boy.

"Fat policeman," he cries; "Red Mustache and Long Nose and Blue Coat are drunk, and are disturbing my _gir_. Come quickly, O Lord, fat policeman."

The mayor sighs. "I go"; then he turns to us. "Will you accompany me?"

"Gladly, if we don't have to eat any more."

The mayor considers this a back-handed compliment to the amplitude of his hospitality and smiles.

"_V period_, it is not far."

He puts on his huge greatcoat, draws on his ponderous boots, takes a heavy stick, and in vividly embroidered Chinese ear-tabs stands ready to follow the Mongol. We shoulder open the felted door. From the low-ceilinged recess between this and the outer door he produces two other big sticks, like pilgrim's staves. These he hands to his visitors.

“For the dogs!” he explains.

The Mongol’s hut is soon reached. It is in frightful disorder, and vodka-bottles are strewn around. The mayor looks up in a little book to see if Krasni, young Agueff, and Pugachev are not, as he suspects, the men who in native nomenclature are called Red Mustache, Blue Coat, and Long Nose. He finds that he has rightly surmised.

“I know them,” says the mayor. “They will come around to me in the morning. I will tell them to make the Mongol satisfaction. When they come back and say he is satisfied, I tell them to be good and to do this no more. _Nietchevo!_”

The irate man is jollied along, and is told that it will be fixed up soon. Consoled and soothed by the protection of authority, he admits it was not so bad after all, and he bids us, as we leave, a grinning “_Sein oh!_”

“Now,” says the mayor, “will you not come and see Urga at night?”

He leads along an icy back street, black as a canyon, with the bulging mud-plastered walls, twenty feet in height, so close that a cart can barely pass between them. Not a light is seen save as a ray pierces the shuttered planking of some compound door. Distant clanging of cymbals and far-off echoes alone break the stillness. Out from the gloom of the street we come into the open _piazza_, half a verst wide. It is unshadowed, and less dark. Threading the heaped-up refuse we stumble on. The black crows, with lancet-like blood-red beaks, which search the heaps by day, are gone. The black cannibal dogs wake and growl as we approach.

“They are afraid of a stick and don’t generally attack people. But, if several do come at you, crouch down and stay perfectly quiet,” the mayor counsels.

He then tells of the Cossack who last year, passing by a dog that did not move aside, drew his sabre and struck the beast. As soon as the other dogs smelled the fresh blood, they became mad, and half a dozen came at him. He put his back against the wall and slashed among them. Many he cut and wounded, but more came and more, in an instant. Soon he was pulled down, for hundreds were upon him.

A big black-furred brute looks insolently at us as we pass.

“They do not bury the dead here, you know,” the mayor says. “The corpses are taken to the mountain northward outside the town, and are left. It is cold to-night. There will be death in the market-place where the poor lie shelterless. And the dogs wait beside them.”

A little way off, where the prayer-wheel stands, is the twinkling light of a shrine. The new moon and the few brilliant stars are frigidly distant. They cast a pale white glow now on the dimly outlined walls and huts. A beggar, lying unseen, calls suddenly as we pass his heap of sodden hides. The six-foot Siberian hunter by our side cries out as he stumbles over and beholds a something, partly eaten, guarded by a great cannibal dog.

If the thought of the rights of man has drowned sympathy with all that concerns the government of Russia, visit Urga at night, and the Cossack of the Russian Guard, swaggering along among the Chinamen,--this Cossack whom you have heard execrated as the “knout of the Czar,”--will look to you like a Highlander at Lucknow. The chance to absorb an unwholesome amount of tannin by way of a samovar, and to sleep on the floor beside the oven in the whitewashed house of Michael Varlakoff, will become a privilege more prized than any possessed by His Holiness, the Living God.

The section of the Russian colony in which we have been lodging consists of five hundred-odd traders. They have drifted down from Siberia, and on the free ground of taxless Urga have established their shops of gaudy European cloths, enameled cooking-utensils, candles, and cutlery. These Russians, whose whitewashed many-paned houses fill a quarter of the town, have not the large interests watched by the English merchants, who dot the globe with their agencies. They are small Trans-Baikal shopkeepers, transplanted bodily. They build their houses in the Siberian way, and their wives toil personally at the oven. They wear blouses and felt boots as the house-dress, and keep the ikons in the corner. Prosperity is evidenced in the striking-clocks, the lamps, nickeled samovars, and curtained double windows. But they are still not many removes from the peasant.

There is, however, another section of Urga’s Russian colony, grouped around the consulate, a large compound situated a verst east of the Mongol town, which was built in 1863, and was fortified in 1900, against the Boxers. Within this compound are the Orthodox Church, the Russian doctor, the rooms of the twenty Cossacks of the Guard, and the great empty barracks of the two _sotnias_ that were sent here in Boxer times, and were, to the regret of their compatriots, later removed. The barracks are still

ready for any future visits, and the breastwork, with its stake and fosse lined with barbed-wire, is equal to any force which from a five-hundred-verst radius can assemble against it.

In this quarter, the Russian consul is autocrat. He is the official notary, without whose stamp no contract is legal, the chief of police, the guardian of orphans. Around him revolves the society of the few dozen mondaines of Urga, whose personnel consists of the officials, the garrison officers, and some half-dozen commercial agents, single generally, or with distant families. They conduct their bachelor quarters through Chinese servants, and their cuisines are helped out by all the canned and bottled delicacies that can be ordered from the frontier. The gold-mines, and the extensive wool-trade which produces a commerce of twenty to thirty millions, demand that first-grade men watch the interests of the great companies which handle the business. So men of the best cosmopolitan Russian type come, at salaries proportioned to their sacrifice. They gather in the consulate evenings, or sit in the fenced-off boxes at the theatrical performances, which periodically come down from Kiahta.

A few families who have made their sixteen-day camel-trip from Kalgan and Peking have foregathered here with their household goods and gods.

Buttressed by the companionship of books, this other class lives in splendidly-furnished rooms, with pictures purchased in Paris, statuettes from Rome, and grand pianos drawn for days over the passes by laboring oxen. One converses at the consulate in French, the mother tongue of none, but the common tongue of all. The few favored guests, who are invited of necessity over and over, play chess endlessly in the evenings. The ladies read the latest French novels, or sing the songs that distant friends have sent from the Riviera or St. Petersburg.

They drive in imported carriages and sleighs for the afternoon airing, and bemoan Nice and Monte Carlo in winter over the pages of Zola's "Rome." The men subscribe extensively to English, French, German, and Russian periodicals. They invite such relatives as can be persuaded for lengthy stays, and shower a guest with the hospitality of old claret, caviar, and the varied courtesies which the rarity of visitors from the world inspires. They take long adventurous horseback trips in the dull season,--explore forgotten monasteries, study the Tibetan inscriptions, print monographs on the folk-tales, and dream of promotion and Petersburg.

The consulate has one uniquely circumstanced personality, whose career is a romance of Eastern adventure. Born in the Baltic provinces, he studied in the Oriental training-schools, and entered the Russian diplomatic service at Peking. Here he applied himself indefatigably, until he knew the Chinese language as did hardly another European. He could write the ten thousand ideographs, and could speak flawlessly the Mandarin and the popular dialects. He went to Mongolia and mastered its languages also,--its spoken idioms and its written grapevine letters. Then, with his diplomatic entrée, his knowledge of men and tongues, and the initiative of an adventurer, he launched his grand coup in the palace of Peking.

He carried away the sole right to the gold of two _eimucks_, a territory as large as France. Not a Chinaman may pan the metal, not a Slav may open a mine, save through this concessionnaire. A third of all gold washed,--these are his terms to those who would lease from him; just double what he pays the Peking Yamen for his privilege. Fortune upon fortune he is reported to have made, and the Chinese gold-washers and the Russian miners who lease from him have gathered their own stakes, too, despite the Cæsar's tribute which he exacpts of all that they produce.

He has spent large sums in bringing down machinery, to do on a great scale what the shallow veins of ore demanded should be done on a limited scale. An abandoned gold-dredge lies far up the Iro River, transported piecemeal at exorbitant expense over the hills. Traction-engines are here, which could not cope with the Mongol roads. They consumed forty days going one hundred and twenty miles to the largest mine. Now they lie rusting in their sheds. Thousands of ox-carts were engaged for hauling in the various purchases. River steamers and great oil-drills scattered over northern Mongolia are relics of his ambition.

His brick house, finely furnished, and his brick smelter stand hard-by the consulate. The Russians tell of masons imported from Sweden to build them. The life-history is a bizarre record of great things attempted by a man whose overleaping ambition stopped nowhere, and whose expenditures more than once brought him down. But his interesting meteoric career continues, and twenty _pud_ of gold are said still to come down yearly from the mines to the most picturesque character in Russian Urga.

We drive down with one of the officials, to be present at another of the events in Urga's meagre happenings--the arrival of the mail.

The Russian post, one delivery a week, crosses Mongolia. The horses bring in three mails from the Russian frontier. From Urga to Kalgan, the camel-post guarded by Cossacks, traverses the great desert of Gobi. Save the Imperial Chinese telegraph, it is the only regular method of intercourse with the outside world. The two thousand-odd roubles a year paid by Russia as a subsidy are a small

expenditure for the opportunity of accustoming the people to her service, and for controlling the avenues of news and communication.

The post-office is at the consulate, and a new postmaster has just been installed. Thereby hangs a tale which is poured into your ear before your stay in Urga has been much protracted.

A telegram came from Irkutsk to seize and bring to Verhneudinsk as propagandists the postmaster's son and daughter--twenty-one and eighteen. Twenty Cossacks surrounded the house at three in the morning. The two were arrested, taken to the mayor's house, and lodged there. The next day they were started on the trail to Kiahta. Once over the border, there would be no more hope. Quickly the leading men of the colony assembled and telegraphed the Russian ambassador at Peking, knowing that if the ambassador had official cognizance, he could not safely authorize an arrest on Chinese soil by the Cossacks of the Guard. The response was delayed, but there was pressure enough upon the consul to get the prisoners held at the mining-camp beyond Iro until the answer was received. At length the ambassador replied that Chinese suzerainty must be respected. The two were free. But the father had been advised to resign his post and accept a station which was offered him at Kalgan, where there were only three Russians, all warranted proof against propaganda.

Beyond the Russian consulate, six versts, is the Chinese town called, as are many of these trading-posts, Maimachen, or place of trade. One can get there by the solitary Cossack-driven droshky that the Russian colony supports. But more appropriately we go on pony-back, borrowing an army-saddle and a purple fleece-lined _shuba_, whose skirts reach around the knees, and whose long sleeves fold over the hands, keeping a rider reasonably warm in cold weather.

The houses of Mongol Urga are soon left behind, the stockaded lamasery is passed on the left, and we are on a big open plain. A few minutes' gallop takes us past the consulate. Beyond it stands a compound girded by a stockade of saplings, within which are the low mud walls of straggling houses, amid which the gilded eaves of a more pretentious residence lift themselves above the rest.

A troop of pig-tailed horsemen trots past: the white tunics of the riders are covered, back and breast, with red ideograph letters, which stigmatize the bearers as of the lowest caste--soldiers of the Celestial service. The man in front holds aloft a gilded pear-shaped standard, and between the ranks lumbers a covered cart with closed shutters. The cavalcade wheels to the right and turns in, dipping the standard as they pass under the gargoyle-tipped beams of the gateway. Servants come running out of the great house. From the cart is helped down a Manchu of pallid face and short gray mustache. That wooden house, girded by mud huts, is the seat of government for this greatest _eimuck_ in Mongolia. The figure robed in cheap blue cotton is lord of life and death, the _Zinzin_, Viceroy for the Emperor of China.

This Manchu Viceroy, and his _Tu-T'ung_, or lieutenant-governor, who represents Chinese authority in the city of Kalgan, are responsible for the collection of tribute, the administration of justice in the cities, and the maintenance of order. Over the Chinese inhabitants in the Maimachen the rule through the agency of the prefect of police appointed by the Viceroy is direct and absolute.

Over the Mongols, Chinese rule is exercised in an irregular nebulous fashion, with some force in the centres and almost none in the outlying districts, where the old nomad organization of society, with princes, barons, or _tai-tsi_, clergy, and ordinary black men, still persists. A code of Chinese laws exists, but in general justice is dealt out by the local princes, or _guns_, who receive also the cattle-tax in some districts, and who go by turns for a year to Peking in symbol of homage.

[Illustration: CHINESE MANDARIN]

[Illustration: GIGIN, THE LIVING BUDDHA]

These Mongol _guns_, ruling over each of the _hushouns_, or counties, which compose the _eimucks_, are under feudal obligations to the Chinese Emperor. Their visible subjection to China consists of ceremonial visits with tribute, for which the Emperor's return gifts are of far greater value. A total of one hundred and twenty thousand _lens_ of silver ($90,000) goes yearly from the Emperor to the nomad nobility. A khan of the first rank receives two thousand _lens_ ($1500) and twenty-five pieces of silk; lesser gentry in proportion.

This primitive aristocracy lives in barbaric state, with splendid carpets, silver-inlaid furniture, and jeweled accoutrements. The women are sometimes very good-looking. They are laden with ornaments, furs and silks, and have a spot of carmine on each cheek, which is the prerogative of a princess. But the normal imagination does not go beyond the gir as a dwelling. Finely fitted it may be, yet it remains a one-room hut, with the open brazier in its centre. Their wealth is in ancestral ornaments, and in the flocks

and herds of their private domains. Their one relic and memorial of a past sway lies in the custom under which the Chinese rulers call by the old Mongol names the _eimucks_, which were the ancestors' kingdoms. That of which Urga is capital still bears the name of Tu-she-tu.

The Mongol lords are responsible for the feudal army, and a caste of bannermen exists, who are paid nominally two ounces of silver per month and a supply of grain, with the corresponding duty of keeping their bows and arrows in order. In the Tu-she-tu khanate of the eastern Khalka tribes, there are twenty banners, each under an hereditary _yassak_, or tributary prince. In 1900 some banners of the Barukhs turned out to fight Russians, but they made no showing whatever, and hurriedly returned after a skirmish with the Cossacks. Spears and arrows are the only weapons the Mongol army can show.

While this feudal system applies in general to the whole _eimuck_, in Urga the Gigin has a unique position. The city is a great monastery, practically all of the permanent native population of fifteen thousand being priests. The laymen who are there are mostly pilgrims, or dependents upon the Church. Over these the Gigin is master, so that Urga is known as "The Holy Living God's Encampment."

Over the Russians and the Buriat tribesmen, the Chinese have no actual sway, and from them they collect no taxes. The Russian consul is dictator to this little flock; and behind his stockade, where the tricolor waves, rally the Orthodox in times of danger.

Across from the _Zinzin's_ doorway is a spiked stockade. Inside, where they have been thrust through a hole just big enough for a man's body, are the miserable criminals. In the big pit dug with their naked hands, the wretches cower, shelterless, under the terrible cold of winter. They live or die there, sometimes fed by the charity of Mongols, sometimes forgotten, sometimes purchasing miserable fragments of offal with the unstolen remnants of the prison allowance. Few waste sympathy on the inmates. The low level of existence of those outside makes the place perhaps less terrible than it would be to people who had known other conditions. It is a grim Chinese jest, this loathsome prison for those who have stolen bread in the market-place, set opposite the palace of the grafting governor who has filched the tribute of Tu-she-tu.

From the Chinese city now, there begins to come the distant throb of drums and clash of cymbals. Three gorgeous Mongols gallop past in their splendid free-reined horsemanship. A sentry stalks to the door of the stockaded prison, and looks toward the gray walls and temples of Maimachen. The procession of the New Moon is to pass to-day.

You leap onto your little Mongol riding-pony, and spurring him into a gallop, hasten along the way to the Chinese city. He tears down the broad road. The resplendent trotting horsemen take the pace as a challenge, and yell joyfully for a race as their whips come down on their own horses' flanks. Mongol girls walking hand in hand along the highway scatter and call out as the riders clatter by. It is contagious. Soon a score of riders are shouting, shaking bridles, and lashing ponies, and it is a cavalcade of racers that gallops up to the gate of Maimachen.

How different is this Chinese settlement from Mongol Urga! It is a magnified replica of the city at the frontiers. Instead of the straggly avenues a hundred yards broad, with cañon-like alleys flanked by high mud walls, all the streets are so narrow that two strides cross them. They are lined with miniature booths. Through the bars of their paper-paned windows one sees the little delicately-tinted pictures of pagodas and of Chinese girls, in quaint sweeping outlines. Red and black and gold, the New Year placards flame on every post and wall. Lanterns are hung before the gateways; green saplings stand sentinel by the doors; and in the unshuttered compounds innumerable lines of gaudy banners are seen, strung from side to side across the courtyards. From the houses come from time to time a thrumming and a picking of strings in minor music, broken by an occasional clang of cymbals or a drone of beaten drums. You pass a temple of marvelously carved wood, wrought into curves and flowers and arabesques, with eaves turning out into open-mouthed dragons. Everything is brilliant in paint and gilt--a blazing kaleidoscope of color.

In a friendly courtyard the horses are tied, and you walk into the teeming streets. All the Chinese of Maimachen and half the Mongols of Urga have come out to-day. Here is a little shifty-eyed Chinese clerk, in his low shoes, with white soles several inches thick, his white stockings, tied at the ankle, showing below the baggy trousers.

Here is a young Mongol lama, who hails you gleefully with a Russian word which he has learned from a Buriat, and points out where the procession will emerge. A Mongol woman passes, gorgeously dressed in flowered yellow silk, with red, sable-cuffed sleeves so long as nearly to touch the ground, and her head cuirassed with the burden of silver ornaments. She smiles at the burly Mongol camel-driver who so openly admires her.

A Chinese merchant, with red-buttoned cap, attended by a servant, is pushing through the crowd. His looks are surly; perhaps he is thinking of the whereabouts of his own establishment in this carnival.

Though the rich and wifeless Chinese may acquire Mongol companions, they cannot buy or give affection. For a poor Mongol, who has the sincerity and humanness which the Chinaman withholds, one of these Mongol concubines will either deceive her master, or, if he object too vigorously, will strip herself of his presents and go to her lover's _gir_.

A big Celestial with a fuse comes hastily through the gateway from which the procession is to emerge. The crash of his firecrackers startles the Mongol ponies pushed close along the houses. Beneath the multi-colored gateway, next pour out a score of horsemen with pennanted spears. They ride two by two, in white coats with red letters on their breasts. Then comes a crowd of footmen, who fill the street in a torrent. The curious Mongols press to each side, and watch the procession of their alien overlords. Two ranks are robed in vivid red, and carry poles with big gold knobs. Blue-coated Chinamen, with cymbals and shrilling fifes, follow; then come more horsemen; then the great silken umbrella, and a gray-mustached dignitary on horseback,--the chief of police; next, more fifers and wand-carriers, six abreast. With fireworks and clashing music, the vivid ranks in red and blue, and yellow and gold, and green and purple, and every other conceivable combination of hues, make their way around the stockade and back again through the gated city.

The crowd seems to be trending now toward a brilliantly colored archway spanning the main street. With the Mongol holiday-makers we follow along into a cloistered courtyard flanked by peaked temple-like houses. A crowd of Chinese is pressing around some one clad in blue, who has just stepped out between the beater of a tom-tom and an artist with a big pair of cymbals. A preliminary flourish introduces the performer--a pasty-faced young Chinaman. He starts a rhythmic chant whose cadence is within a note or two of one of the old crooning Negro melodies of our South. Over and over again he chants it. A poet this is. He has conned his verses, and now comes out to sing them. He ends with a special swirl in what is evidently a very comic climax. The drum and cymbals crash out once more, and another chanter comes--this one old and feeble, with a curiously penetrating voice. He drones a long hexameter-footed epic, in which the harsh Chinese _gh_ and _wh_ sounds are not so coarsely enunciated as in the poem of the first reciter. "That is one of the old legend-singers," you are told. It is such a ballad as Homer sang, or the Welsh bards chanted. It is the poetry and the history of the long past, the immemorial past, far before the infancy of other nations; for China keeps alive her antiquity, and in her old age never forgets.

[Illustration: CHINESE ARCHWAY, URGA MAIMACHEN]

This week there can be no buying or selling. The Moon must be honored, but visits are in order. Your friend brings you to meet a leading Chinese merchant. At the house, a grille of thick wooden bars runs down to the street level from the eaves just above one's head. Looking through them, one can see over the little square window the most delicately-traced pictures on a white background. The panes are of paper, all save one, which is of glass, so that the owner may see if, coming down the street, any one turns and climbs the three steps into the ordinarily wide-open door of his house.

The home of our host, which is likewise his office, is finely fitted up and faultlessly clean. His light-blue silk robes are immaculate. Two servants wait at table, bringing in the best of China tea and French "petit-beurre" biscuits for our delectation. Everything is appetizing and orderly.

As we are sitting over the cups with the Chinese merchant, the boy comes to announce visitors, and two blue-robed fellow countrymen enter. One has a strip of light-blue silk laid over his two arms, which he stretches out. The host extends his own arms and receives it, then gives it back to the newcomer, who goes down on one knee and again presents it. The merchant takes it a second time and bows, this time retaining it. The two guests bend and leave the room. "New Year's presents," the merchant explains. Again the boy comes in and announces a guest. A Mongol messenger enters, goes down on one knee, and presents a red slip, black-lettered. "Visiting-card," the host explains. Then, with a smile, "White, like yours, not polite." He accepts this too. "_Ch'ou Ta-tzu!_" (the dirty Tatar!) he says as the latter leaves.

The calls continue, and our visit. The host is charming, cultured, educated; he speaks English well, and lacks in no attention. But you wonder if, when you leave, he is not going to murmur about you, "Yong-kwei-tsz!" (foreign devil!)

Throughout all intercourse with these Chinese, one has always the uneasy consciousness that one is doubtless, as with the card, unwittingly offending. There are three hundred rules of ceremony, three thousand formulæ of behavior, regulated by a classic tradition. The ritual is so drilled into the Chinese as to become instinctive. Celestial breeding would dictate that the little formalism

which precedes a rubber, “May I play to hearts, if you please?” be stretched to cover every action of life. The left, not the right, is the place of honor, and to enter a room facing wrongly is a slight. An irregular method of folding a red New-Year’s card, and the failure in writing to raise one character above the level of the rest, are breaches of etiquette.

For our race there is always felt, behind the soul-mask of Chinese eyes, a contempt. The kindness of our host to-day is unfailing. Yet we are not at ease or sure of the ground. Errors, condoned to keep face, are often inwardly resented. If you put your hat on the Mongol’s altar, everybody in the hut will yell out for you to take it off. When you remove it, they will nod understandingly as the interpreter explains that the ignorant foreigner transgressed inadvertently. Forthwith all is forgotten in an enthusiastic discussion of the last case of botts among the horses. But with these Chinese one can never tell if, by taking a chop-stick between the wrong fingers, one has not intimated that the host’s grandfather was a cross-eyed coolie soldier. No one will challenge or set a man right, but the breach will be silently resented, though the tea continues to be smilingly offered.

The old-time Chinese dealers at Urga grew enormously wealthy in the tea-trade to Kiahta. These have mostly gone back to China. But there are still a number of the better-class merchants whose wares are sold to the traders and by them to the Mongols. The house of Liu-Shang-Yuan claims two hundred years of establishment. The Urga people are still prosperous, for great sums in religious tribute come from all Mongolia to this Lourdes of Lamaism. There are also many Chinamen who make large profits from wool.

Of a total trade in Urga estimated at twenty-five million roubles per year, nine tenths is in the hands of Celestials. The remainder is Russian, for the Mongols are entirely without a merchant class. Of the exports, wool is the main item. Some two hundred thousand _puds_ are sent from Urga annually, four fifths of which go to the United States. While cotton cloth, cutlery, kitchen-utensils, and other European goods come down from Russia, the bulk of the imports are brought from China by caravan, through Kalgan. Silks come from Shanghai, and tea from Hankow, passing via Peking. There is trade, too, with Ulasati in western Mongolia. It is the centre of a fur and hide country which is isolated from outlets toward Russia by the high mountains, and must send caravans to Kiahta. Its communication with China is either by Urga and Kalgan, or by the caravan-route further south.

When the holiday-time is over we see more of the Chinese traders. Sitting in the shops, with one of these, and glancing out over the little counter of the sales-room, we converse as the customers come and go.

The Russian in his shop shows all he has of wares, the red and magenta cloths, the enameled kettles, the cutlery and sweetmeats. But the Chinaman wraps his goods in hieroglyphic-covered papers, and all that can be seen are rows of long-stemmed brass-bowled pipes, and an array of silver and bronze teapots on shelves at one side. Very rare things, too, our Chinese host can produce. Shanghai silks of finest texture, ten roubles the _arsheen_; jade mouthpieces for the pipes at a hundred _taels_; Hankow tea culled from the tenderest shoots. Everything is labeled and systematized in the Chinaman’s place, and he goes at once to the packet which he wishes to show.

A dozen Chinese, with bright blue silk jackets over their black surtouts, invade now the home of the merchant. The red knot on their black skull-caps and the length of their queues and finger-nails show them to be men of some importance. They take off the bright-colored ear-tabs as they enter. They are down to buy wool. To-day they visit, next week they will trade. Then all but one will sit in the outer shop, while the spokesman alone will go into the inner room and confer with the merchant. From time to time the spokesman will go back to the party and consult, till in the end the bargain is made. They will all hold to the agreement, too, whichever way the market goes. For in this the Chinese are inflexibly honest. A local Chinaman dispatched a mounted messenger the six versts to Urga, to return to us twenty kopecks which he had overcharged by a slip of his abacus-adder.

Yet the Scotch engineers saw shells in the arsenals loaded with clay when the native troops went against the Japanese. The English miners in the Province of Shan-tung have had their profits cut to nothing by the official “squeezes,” and Chinese have bought in the depreciated stocks.

The ethic code of the squeeze seems to be very nice. It is a point of honor, almost always scrupulously observed, that the first-fruits of official graft go to repaying the one who advanced the money to buy the office. A Chinaman, who could not be trusted to administer honestly a trust fund of a hundred _taels_, will repay this obligation to his backer. Thus must he keep face.

From the tax-appraiser who numbers the sheep to the civil governor who receives the lumps of silver tribute for transmission to Peking, every official gets his squeeze. They say in the _eimuck_ of Ulasati, where sables are part of the tribute, that the officials take out the best furs and put back poor skins to keep the number the same; and in Urga, that the enormously rich administration

takes a Tammany third of the tribute. There has never been a viceroy yet, it is reported, who has left Mongolia poor. Yet each official plays straight with his backer, his “belly-band.” Very curious is this race, and there live few Westerners who can at all understand it.

We ride back in the evening from the Chinese city (for none may stay for the night), buried in recurring reveries. How brightly glitters the face, and how barren is the heart in Maimachen! Never the thousand ties of kinship and affection, never the thrill of citizenship, never the love of a home. How little generosity, too, or sympathy for the people of the land! The Mongols are but “tame barbarians,” as of old were stigmatized the tributary Formosans. Now and then one finds a Chinaman out among the nomad Mongols. Perhaps he may be a watcher at a distant temple, perhaps a telegraph-operator on the two lines that go, one to Kalgan and Peking, one to Kiahta and Russia. Always he is something solitary--different. There is an almost sinister splendor in this aloofness--this self-sufficiency of walled cities and compounds where none but Chinese may dwell. What a rebuff of nationhood in the gates that shut out at night all save the alien outlanders! What contempt in the law that no woman of China may come among these Mongol people, as if the very air were contamination! How the natives are silently despised, whose bodies in death go to the dogs, while the Chinaman’s, in a casket, is sent back over the long leagues to his home!

The homeless, wifeless, Chinese city, with the quarter of Mongol women without the walls,--it is in many ways typical of all Chinese rule in Mongolia. For, as the Celestial trader defaults in the duty of marrying the Mongol mother of his children, so China defaults in many of the duties that are inherent in suzerainty. One resents the heavy Chinese yoke on the necks of these simple frank-hearted Mongolians. They are a race of great good-humored children, and they are exploited while disdained.

We are thinking of this unfairness as we ride back along the road to Urga. Behind is the distant Chinese city, the Manchu Viceroy’s straggling palace, the picketed prison-stockade. Before is the drooping tricolor banner of the Czar, and the white and green of the Greek Church, with its far-seen golden crucifix. A crowd of brilliantly-clad Mongols, lamas and laymen and girls and youths, are strolling back from Maimachen. They are laughing and chattering, and in uncouth playfulness are pushing one another about across the road.

Half a dozen of the _Zinzin’s_ Chinese foot-guard are likewise coming from Urga, stolid-faced, superior. As they reach the tumultuous band it sinks into silence, and the men crowd to the side of the road that the Chinese may pass.

[Illustration: THE GREAT WALL]

They tramp by without a glance. Then out from the Russian barrack-gate swings a little Cossack in his great black sheepskin hat, gray tunic, clattering curved sabre, boots and spurs. He is one of the Zabaikalskaia Buriats, whom Russians call Bratskie, the brotherly people. He speaks a tongue so similar to the Mongol that all these people can understand him. They look up to him as a rich relative, fortunate in overflowing measure. For on the pilgrimages of Buddhist Buriats to Urga, their wives have told the wondering Mongol women of the sewing-machines which they have at home to stitch linings, and have allowed the visitors to peep into their mirrors. The Mongol men have admired the Buriats’ breech-loading rifle, worth six horses at current quotations. They have enviously heard tell that in Russia one pays no cow-_alba_, but the young men get a uniform and free food when they ride out to give their Cossack service to the Czar. They have listened to Buriat boasts of the warm houses of Siberia, and stacks of hay, and stored-up harvests. So Mongols smile when the Buriats come to their _girs_. They say, “Rich smooth Buriats! Great lords! Give candle, give sugar, give tobacco, give vodka.”

Has not a little Zabaikalskaia Buriat reason to swagger when he starts from the Russian barrack-gate to see his lady in Urga? And should a Cossack of the Czar step aside for a Chinaman in the shadow of the Eagles? Head erect, with a look to right and then to left, hand on sabre, he swings straight down the centre of the road, and right through the Chinese soldiers. Without dispute they open a way. He chucks a not unwilling girl under the chin as he passes the Mongols, and he is good-naturedly hailed by the rest: “Hello, Cossack! Why so fast? She has gone away with a lama.” And he goes a bit faster toward Urga.

These Cossacks, terrible in war, friends and equals with the conquered in peace, are those who have held the Russian vanguard in this march to China,--the march which began when the two _hatamans_ of Moscow, commanded by Ivan the Terrible, started in 1507 on their long tramp eastward. The Cossacks it was whom Yermak led to the conquest of Sibir. Through them, in storm and stress, despite oppression and convict-gangs, with faults and failings, omissions and commissions, the advance of Russia has been the way of civilization where none could otherwise have come.

“It will mean much when a Russian railway follows our trail from Kiahta,” says Alexsimevich; and André adds: “They will all be glad when the Cossacks come to Kalgan.”

VII

RUSSIA IN EVOLUTION

New times have come to Russia with the events that have halted her armies. The Slav, looking and reaching outward, has been hurled violently back upon himself, and he turns to look inward. The stream of Slavic civilization still flows eastward. But now held back at the frontiers, its tide is rising behind the impounding barriers and is lifting on its wave the level of national life. Its scour is undermining here and there, its laden currents are depositing and filling in the interstices of the social fabric. The struggle is intensified to achieve representative government, to secure administrative reform, to relieve the distress of the peasantry. The people are in evolutionary throes and are sweeping forward in the arts of peace, in the science of government, and in the myriad lines of internal development.

The movements of empire-advance have been noted because they have been conspicuously visualized. But the economic and social growth have been only slightly regarded by our western world, intent upon great events, crises, conflicts lost and won. The seizure of a hamlet in Manchuria has obscured the founding of twenty cities in Siberia.

The continent-cleaving Siberian Railway has now revealed, in the Russian occupation of northern Asia, not an exploiting colonial enterprise, but a race-movement akin to the European invasion of our Aryan ancestors. The upward struggle of a people striving to find itself is embodied in imperial rescripts and armed revolts, in dumas and dynamite, where rival titans grapple for the throw. There is now therefore in the world a more earnest watching of this metamorphosing Russian people. What are the types of civilization, the beliefs, the manners of thought, the institutions that are to hold mastery over the largest area on the globe occupied by a single nation?

To comprehend a people and the course of its evolution one must pierce below the surface of ephemeral and contemporary incident, and probe the primitive racial elements. Russia is to-day iceberg-like. The crumbling, upper ice, honeycombed by eating waves, is exposed; but submerged and unseen is the massive blue block beneath. Because rotten surface-structures are obvious, many fail to appreciate what lies in the depths. There comes understanding for much when one sounds the ancient sources in race-history.

From the earliest times Russia lay across the path of incessant invasion from Asia. In 1224 the Mongols swept down upon the old Scythian plains. There were no mountain fastnesses in which the sparse population could defend itself. The followers of Genghis Khan, through the years that followed, destroyed town after town,--Bolgari, Suzdal, Yaroslavl, Tver,--devastated Volkynia, and Galicia, until all Russia, save Novgorod, was brought under Tatar rule. Their devastations cut off the population of whole provinces, and changed old Russian cities, such as Kiev, to hybrid towns of Asiatics. At Sarai on the Volga, for two centuries Tatar sovereigns ruled; and here from being pagan they became adherents of Islam. Russia’s foreign master was confirmed in a religion as antagonistic as was his race. To these aliens Russia gave humiliating homage and paid tribute, and from their khans her czar received permit to rule. Thus in her infancy she had a foreign race, not as servile members of the humble labor class, but in the wild, fierce scourge of conquerors.

Throughout this period many Russian princes married into noble Mongol families, and Mongol officers formed alliances with the Russian boyars. The Muscovite aristocracy had already grown into strong Oriental proclivities from contact with its southern neighbor, the Byzantine, and these became confirmed under the Tatar. One czar, at least, Boris Godunov, was of Mongol birth. Incessant war harassed the people. Alexander Nevski, of Novgorod, beat back the Swedes; but, abasing himself, he went to the Tatar khan with the tribute of a country too feeble still to resist him. By and by Russia began to rally and to strengthen her centres, Novgorod, Kiev, and Vladimir. Moscow arose--that small destiny-city where Simon the Proud, even in vassalage, dared to dream of unity and nationality, and took the title of “Prince of all the Russias.” His grandson made the first great stand against the Mongols and won in the field of Tula, which, with the fights of Alexander Nevski, gives to chroniclers and bards their early Russian ballads, or _bilinî_. Moscow, punished cruelly, was razed almost to the ground. But the Bear was aroused and goaded into desperation. Russia reeled to her feet, and for nearly a hundred years she fought, she lost, she fell; but she rose again and fought on, until at last the power of the Tatar terror was broken and the tyrant was driven over her border. Still, for a hundred years more, she was forcing back his inroads, and rescuing the winding trains of her children, toiling over the southern steppes to be sold as slaves at

Kaffa. This was Russia in the last quarter of the sixteenth century.

That Europe was spared this, she owes to the Russian. Through those crucial centuries when the Slav, weak, torn, anguished, beset with foes around and foes within, was standing grimly at the perilous portal of civilization, Europe, within the temple, safe by his grace, was privileged to work up into light, to cement her nationalities, to effect the liberation of her masses, and to develop her intellect into the magnificent promise of a printing-press, a people's Bible, and a Shakespeare.

But to the brave warden of that portal there was not the sweetness and the light. For him were the seams and the scars, the mutinous passions of the strife. Long after the clouds of the Dark Ages had cleared from the face of western Europe, they hung over Russia. The Slav was back in his Dark Ages yet, heir only to a barbaric experience. Here he must start, where Europe had started nearly a thousand years before, where America, in the favor of Providence, was never to be called upon to start. For him were the memories of subjection and the blood of contention; but also, in relief, to him were the stolid patience and endurance which were to serve him so well. He groped along in the shadow until the coming of the great Peter.

But now arose a man. He, too, had dreamed the dream of empire,--vast, masterful. He set about making his dream real. He found Russia a small inland state, torn by faction, barbarian, and Oriental. Though himself the descendant of a long line of Byzantine kings, half monk, half emperor, he saw with the insight of genius, and he knew that that way did not lie greatness. Therefore fully and fiercely he broke with the past and set himself to the future.

Between him and that future stood the Strelitz. The walls of the Kremlin, and the Red Square told the doom of their barring conservatism. He warred with the Turk, he fought the Cossack, he routed the Swedes, again and again, taking whole provinces on his Baltic outlet and securing the coveted Neva. He embroiled himself with Persia, and through Baku opened a way to the Caspian. Then, with a high hand, he swept out the customs that made for Orientalism. He broke the seclusion of women, the prostrations, banished the caftan, the beard, and the flowing robes. He lifted his people bodily and violently out of their past, and set them down face-front to a new order. The Russia he had received a province, he left an empire. The Russia he had received Asiatic, he left European, and already a force in Europe. And when arose one of his own blood--a reversal--who would undo the herculean labor of this master-builder, who would give back to Sweden those priceless, wave-washed Baltic provinces, and, restoring the capital to Moscow, return to an Oriental estate, the patriot was stronger than the father, and at the price of his son's life he bought the progress of Russia. Here in this man, who died in 1725, we can truly say that Modern Russia begins.

Through this skeleton history can be traced the structure of the modern state, as in the struggle for survival may be found the root and early warrant of her governmental system. Every element, physical and ethnic, was, and still is, a handicap. Russia is not protected by the ramparts of the sea; she is surrounded on all sides by nations with whom her history has been that of perennial conflict. In place of a compacted, well-peopled country, she has an empire extended gradually from frozen Nova Zembla to Afghanistan, from the Danube mouth to Behring's arctic sea. She is a land of many distinct peoples, as foreign to each other as Lithuanians and wild Kirghis; as alien in religion as Catholic and Mohammedan. She is divided into one knows not how many tribes, numbers of them completely barbarous. Her eastern and south-eastern frontiers call for defense across vast and vacant stretches. Her northern and western borders are occupied by Finns and Poles, unforgetful forever of their own days of sovereignty, naturally and rightly jealous for the memories and the prerogatives that are its legacy.

With the eastern problem living from the first on her immediate border, with her many tribes wayward, Russia early strove to fuse her empire into national unity. In old Poland had been seen the fearful price which feebleness and disunion pay to fate. How much greater was the menace to polyglot Russia, were her master-grip to relax! That she should hold a strong hand over the elements that ever threatened her disruption was the first national necessity. This supreme obligation to herself in her entirety compelled a firm, commanding, centralized authority. The mould that was to shape such metal had need of rigidity and unyielding strength. To meet these race-desires, not as a purposeless tyranny but as the fruit of a long evolving system, arose the autocracy.

The system reached its climax in the most absolute administration of modern times at the period of the American Revolution; the "Government Statute of 1775" meshed all things and all men into the institutions of despotism; Russia groaned under the iron rule of a Nicholas, yet rejoiced in the belief that strength was there, and sure defense from domestic disunion and foreign aggression; then, in the Crimea, came a revelation of the inefficiency of the bureaucratic juggernaut. Despite the stubborn valor of the defenders of Sevastopol, despite the gallant efforts of the aged autocrat, the glory of Russia went down in the blaze of her city and her fleet.

The old régime had failed. Even the Czar, before he died, could read the lesson but could not act. How pathetic the words of the failing monarch: “My successor may do what he will, I cannot change.”

With the accession of Alexander to the throne in 1855, on the sudden death of Nicholas, came the first effective steps toward modern institutions. The young czar, a self-declared friend of progress, raised regally the standard of reform. All Russia rose to the hopes of his idealism. Corruption in office, which had before been rampant, was crushed out by the sheer force of public opinion. Pamphlets circulated freely, uncensored. Meetings were everywhere held to discuss the varied plans of a vivified government. With a whole nation become to a degree transcendental, the Czar began his reign and his reforms.

First of all for righting, as it was first in evil, came serfdom. Summoning commissions of his ablest advisers, seeking counsel of the proprietors and their coöperation in an act of self-abnegation, the Czar proceeded to the execution of his great task. For three years every side and every phase of the problem was studied. Then at length with a fundamental law which forecovered every detail of the situation, Alexander II put his signature, February 19, 1861, to the great Ukase of Liberation.

In Russia’s past there is much to answer for before the judgment-bar, in omission and in commission. Yet, giving but justice to ruler and people, it must be allowed that the measure which freed the serfs ranks, with Magna Charta and the American Constitution, among the mightiest agencies of advance that mankind has ever known. A dependent population of nearly forty-six million souls was given liberty. The great act was accomplished peacefully, and the measures were executed without any trouble worthy of the name, in a spirit equitable to the old owners as well as to the serfs. Not alone were the latter released from bondage, they were provided, one and all, with land and livelihood. They were given, in everything that concerned their local administration, entire freedom from interference by their old masters or by the members of the Administration. The righteous deed that the American Republic achieved nearly three years later liberated but one ninth the number of the Russian bondmen. It did so at the cost of the deadliest fratricidal war of modern times, and the impoverishment of one quarter of its people. All the work of the Freedmen’s Bureau through the Reconstruction period could not insure to a tithe of the Negroes the opportunity for a livelihood,--this that Russia provided inalienably for each of her liberated. To this day the American Negro in many places is under special civic disabilities more galling than those imposed anywhere in the Russian Empire.

The protection of the former serfs was skillfully arranged by grouping them in self-governing village communes, to which land enough was given on a long-term repayment basis. In each, by an assembly composed of all the heads of households, periodic allotments of the common territory were made to the individuals. Compact economic units, whose property could not be sold, were built up against alienation of the land or poverty-induced peonage. The rendering of justice in local disputes was delegated to the peasant courts,--the only tribunals in Russia, save the National Senate, from which there is no appeal.

The Mir, complete within itself, was responsible to the Imperial Government for good order and the taxes, and was secure from molestation provided these duties were fulfilled. Its inhabitants, united and independent, were able to resist any encroachment by their former masters or by neighboring landlords.

[Illustration: THE KREMLIN, MOSCOW]

It is not unworthy of note that up to the present time the liberties in economic matters thus granted have rarely been infringed by the authorities, nor have the village assemblies been exploited as a play in politics or to attain personal ends. While agriculturally and industrially the communal land provisions have become insufficient, cramping, perhaps baneful, and no longer necessary now that society is in equilibrium, nevertheless the germ of free institutions fecundated in the Mir, when dissociated from its communal features, is admirable still, and is capable of becoming the foundation for real self-government.

Plans for provincial assemblies as a further extension of local home rule had been under consideration since 1859. On January 1, 1864, an Imperial Ukase was promulgated instituting Semstvos in thirty-three governments. To this assembly, proprietor and peasant, rich and poor, elected their representatives. Each Semstvo was to appoint its own executive to carry out the laws it decreed.

The jurisdiction of this assembly, though confined to local and non-political matters, was wide. Rates, streets, convocations, posts, sanitary measures, famine-relief, fire-insurance, schools, agricultural improvement, all land, house, and factory taxes (those upon imperial as well as those upon private domains), were given into the Semstvo control. It was granted partial powers over various other minor matters. It exercised practically all the economic and social functions of local governmental activity save what fell to the Mirs. It was welcomed as an epoch-making institution. The liberal press of the period hailed it as a living guidon of the upward way,

as the blessed daylight of a constitutional government.

So indeed it might have become. In the new Emperor's mind there germinated a whole peaceful revolution. He had plans for new courts of justice, reorganization of the army, reform of the civil administration, and popular representative government, with an elected national chamber.

But in the midst of his reforms broke out the Polish insurrection. The Czar had granted to the Poles elective councils in each district of government and in the chief cities; he had appointed a Pole his Minister of Public Instruction, and had made many concessions to their old language. Iron and blood crushed out the insurrection, but it had brought to the great Czar Liberator the conviction that liberty spelled disunion for Russia, and this belief was never to be dispelled.

Upon the Semstvo assemblies, no longer uplifted by the old generous enthusiasm of the sovereign, pressed little by little the dead weight of executive officialdom. One by one their functions were lopped away. More and more the selection of delegates was transferred to the administrative officials. The marshals of noblesse became chairmen, the governors vetoing overlords. Before the death of Alexander II, his once-cherished creations had lapsed from independent state legislatures into anomalous, semi-advisory councils, discussing roads, land-taxes, agriculture, and schools, and controlled by the land-owning nobles and the governors. Semstvo and Mir and Assemblies of the Noblesse became ornamental trimmings to the colossal edifice of the bureaucracy.

The assembling of all the functions of government into the hands of the executive became again the guiding principle of this system. "The Council of State," whose office was that of discussing the budget and law-making proposals, was the simulacrum of a parliament. The Senate, which gave decision on special points appealed from the lower courts, and whose promulgation of all enactments was the hall-mark of their legality, was a form of supreme court. But both hung from above rather than rested on a substructure. They were substantially cut off from popular influences, their function was secondary action following origin in the executive bureaus. The Imperial Autocrat, deriving his right from Divinity alone, exercised, in addition to his executive functions and his duties as supreme commander of the armed forces of the State, those powers which by a segregation of functions would have fallen to the legislative bodies and the judiciary. In this, the ten ministries were his main agencies.

Under this system, legislation was inaugurated through the presentation of a project to the Czar by one of his ministers, or by outside petition, or perhaps by the imperial wish.

The proposed enactment, if the Czar ordered it to be further examined, was referred usually to an Imperial Commission of Study. Debates followed in the Advisory Council of State, and the completed bill, as framed by this body, was signed by the Emperor and became a ukase, to be formally promulgated by the Senate and enrolled as part of the law of the land. Interpretations of law were made by the Ministers, which none might gainsay. Thus was the legislative function absolute.

In the provinces the three functions of government were equally centralized. A governor (almost invariably a general or an admiral) through his subordinate executive officers duplicated in microcosm the system of the capital. The dependent Semstvo was his Council of State, the dependent judges composed his Senate, the dependent Semski Natschalniki, his executive ministers. Into his bureaus came the details of provincial government save such matters as the villagers settled in their own Mirs. The troops of the district were at his call, the gendarmerie under his orders carried out the judicial arrests and the drumhead condemnations that sent so many thousands along the road to Siberia.

In the placing of these proconsuls and their sustaining soldiery was applied the Roman rule, "Divide et impera." The head officials of the provinces were from distant parts,--the Governor of Warsaw from Tiflis, the Governor of Odessa from Samara, the Governor of the Amur from the Baltic. The Orthodox Cossacks of the Don were in force among the troubled Poles and Jews of the western governments; the drafts from the peasantry of Little Russia garrisoned Tiflis and Turkestan, and Siberian regiments watched the Austrian frontier. Even the popes sent to petty village congregations were generally of far-off origin.

Though power was thus alienated from the people, the bureaucracy, by other agencies rooted deep in human nature, had twined itself around the daily life of society.

Every ambitious man in his profession, as he succeeded, was marked for promotion. Not only to office-holders and soldiers, but to everybody, throughout the whole social fabric, were "chins" or graded ranks given. Here for example is a selection from one of the lists of the Czar's Christmas announcements:--

Appointed members of the Council of State: Privy Councilor Kabylinski, and Von Kaufman, Senator, Minister of Public Instruction, President of the Supreme Court.

Decorated with the St. Stanislaus Order, First Class: Major-General Hippolyt Grigerasch, Director of the Department of Physics and Electro-technology at the Nicholas Engineer Academy and School.

Decorated with the St. Vladimir Order of the Third Class: Major-General Michael Hahnenfeldt, on the staff of his Imperial Highness the Supreme Commander of Guards in the St. Petersburg Military District.

Valentin Magorski, Doctor of Veterinary Medicine, Chief of the Veterinary Staff.

Alexander Pomeranzev, Professor of Architecture.

Dimitri Sassiyadke, Governor of Radom.

Michael Mardarjev, Censor of Foreign Papers and Journals.

Advanced to the ranking Chin of actual State Councilor, hereditary “honorable citizen” Constantine Popov, founder and director of the Tea Emporiums.

Raised into hereditary “honorable citizenship” of the 3d gild, the Archangel merchant Emil Brautigam.

Given personal “honorable citizenship,” Vladimir Ritimoun, Proprietor of the Wollner Typographical Establishment; Karl Volter, Captain of the steamer _Emperor Nicholas II_, of the Riga Navigation Co.

When a professor from his books was called up before the highest provincial dignitary to have pinned on his lapel for honorable service to the Empire the Order of St. Stanislaus, it was hard for him not to have a warm sentiment for those who had so signally recognized his talents. When on the document which recorded the promotion of a royal prince to a colonelcy was enrolled the name of a tradesman; when a neighboring doctor was raised his step in civil rank, each felt the touchstone. All who had served well in their respective positions might hope to be on the honor list, and this was the most effective tribute to the weakness, the worth, and the ambition of human nature.

In Russia, as in France under Napoleon’s iron yoke, there was a welcome to every sort of ability, and its elevation to posts of the highest trust. The aristocracy sought for was one of power, not that of a small birth-caste. A fundamental democracy ran through society. Save for a few of the Guards regiments, the army was officered by poor men. The Cossacks’ officers were chosen from among their own people and were state-trained. In the knapsack of every soldier was Skobelov’s baton; in the desk of every chinovnik, Witte’s portfolio.

So stood the bureaucratic edifice, complete in itself. Here and there a popular embellishment was added, perhaps to strengthen, often to conceal; but in grim reality it formed no part of the structure. Thus the Russian Empire finished out the nineteenth century. With the twentieth the system had come to trial for its stewardship.

In the great reckoning are elements both of good and of evil. The liberation of the serfs and all that went with the emancipation stand as a credit. It is a further vast credit that Russia has made, held together, and civilized an empire of over eight and a half million square miles, with a population of over one hundred and forty million souls; that to the internal development of her splendid resources the Government has vigorously set its hand, seeking for her rivers unhampered navigation, for her canals larger passage, for her deserts great irrigation works. Already the Siberian Railway links the Baltic and Pacific; already on the southeast the tracks creep to the threshold of Kashmir, where some four hundred miles separate the Russian lines from those of British India. This gap once crossed, Calcutta becomes but eleven days distant from London. It is still another credit that, despite Slavic limitations and financial loss, in the face of Western invention and competitive leveling, the country of the cheapest telegraph and the cheapest railway rate was until recently not America but Russia. It is a credit that the public land has been put so efficiently and generously at the disposal of the people, that any emigrant expressing a genuine purpose of settling will be given, wherever he may select it in Siberia, a liberal homestead, and he will be conveyed to it over the Trans-Siberian Railway for a sum less than the cost. He is not only allotted his homestead, but he is supplied with seed, grain, tools, and advances for his first years of marketing.

It is again a credit that the governmental attitude to the industrial classes has not been one of oppression. True, work-hours are unrighteously long and certain strikes have been put down arbitrarily. Still the Russian labor laws and arrangements for the settlement of labor difficulties are in many features conspicuously statesmanlike and just. Some years since, a body of Belgian

miners, fifty or more, with their families, were transferred from the collieries of the Meuse to the Donetz Basin. Recently these miners, at a meeting of the directors' board, presented a memorial to this purport: "How happy are we who are no more in Belgium, but who live and work in Russia! No longer must we support the socialistic committee. On the day of pay we put our hands in our pockets and have it for our wives and children."

The other side of the ledger is, however, not without weighty items. While no system of government can legislate prosperity, the public welfare is rightfully the first test, as it should be the first consideration, of an administration. Despite her immense territories, her vast mineral deposits, her fertile soils, her navigable rivers, her abundant timber, all the natural sources of national wealth, Russia is very poor. The peasants have more than doubled in number since the allotment of communal fields that followed the emancipation, and they are in general want. Vast stretches, whole provinces, are subject to periodic famine. Millions of the people are constantly on the brink of starvation. Manufacturing is, as a rule, desultory, undeveloped, and, in general, unprofitable.

The per-capita wealth of Russia is estimated at but two hundred and seventy-five dollars, as compared to Germany's seven hundred dollars, France's eleven hundred and twenty dollars, and England's twelve hundred and thirty-five dollars. The savings-bank deposits reported for all Russia average but $2.75 per man, while in France they average $20.82, in England $15.00, and in Austria $15.68.

The degree of administrative responsibility for this condition is of course not to be definitely laid down. Much manifestly is due to natural conditions, national character, and historic handicaps; and some of the resultants would be the same under any administrative policy. Russia in her great area has had a sparse population. She has not, like her sister nations, and preëminently America, been able to lay the rest of the world under teeming contribution to her citizenship. She has had only her natural increase, and no such record as that of the United States has been possible. The Slav is not commercial, but agricultural. He has remained poor, and has had relatively very small resources to devote to what have proved our two greatest developing forces--internal improvement and education.

It is, however, a matter directly involved in government that, with this low standard of national living, there is the correlated fact of extremely high national expenditure. An immense budget of two billion roubles, ordinary expenditure, is annually met, which the war-loans raised to a total, for some years, of over three billions.

[Illustration: DRAGOON CONSTABLE RUSSIAN TYPES]

It is the general belief that a large part of the public funds is frittered away in needless waste, with multitudes of idling clerks and sinecure officials. Granting the benefit of doubt, assuming that the Administration's corruption and inefficiency are exaggerated, and supposing that the public money is in the main honestly and productively spent, it is still a very serious question if any public service rendered by the agents of Government can correspond to or justify the immense burden of taxation heaped upon a people whose economic distress is so terrible.

The weight of the tax-levy crushing the peasants, whose improvident habits aggravate their want, is, for most, unescapable unless they follow the emigrant's road to Siberia. The rate-gatherer can take anything the mujik has, save his last coat, his last horse, his seed-grain for next year. He is, with fateful frequency, forced to hire himself out to whoever will use his services, and this during the brief summer season which is so supremely essential if he is to attend to his own crops and fields. One landowner relates that he has seen paid an average of five roubles ($2.50) a month for farm-laborers, including men, women, and children, during June, July, and August.

Under the old system the method of rate-levy on the "souls" in a family weighed inequitably. Census revision was delayed in one instance, personally related, by over twenty-three years. A family taxed, twenty-three years before, on a father, four brothers, and two adult sons,--seven souls,--was still assessed for seven males, whether the family had increased to twenty, or been reduced to one. Each member of the household was responsible for the total.

It is related that whole families in Samara, reduced by the fearful cholera epidemic of some years back from scores of men to a dozen or ten, had to leave their home-country for Siberia to escape the load of their dead brothers.

Discussing the economic loss of the years of military service, one of the country nobles related an incident. He told of ordering the dead leaves and branches cleared out of his lake. Ordinarily, he said, he did not go near the work or let the peasants come near his château, for there was a good deal of class-hostility where he lives. But he was interested in the lake because the branches were killing some specially cherished fish, so he went down through the woods and was surprised to see nobody working. All the men

were crowded round a peasant whom he had cited as an example of those who, though unlettered, had great capacity. This man had served seven years in the navy and could neither read nor write, a commentary upon what the service training was. He was declaiming on politics, and the squire stepped behind a tree, for the peasant spoke musically and well. The man was telling about his naval service: “Seven years on the boats I have been, brothers, and every three months I got ninety kopecks to buy a string for the crucifix and to cut my hair. I had no money for tobacco, none to send home to my wife in all this time, and I came home without a kopeck. Seven years of my life I have given to the Czar. What has he given me? What has he given you?” The landowner stepped from behind the tree and faced the group of startled peasants. “You have heard, your honor? Well it is true, it is true!”

The measure which under existing land-conditions would most directly raise the standard of life is the improvement of the mediæval agricultural system, and this depends upon the intelligence of the people at large. Scientific farming needs technical knowledge, yet of the great sums collected, a very small portion goes to education. The Nation spends for it but forty-three million roubles, the Semstvos but twenty million roubles, or together one eighth of the military budget.

A tedious, inefficient course in Slavonic, with the prayer-books as text, a smattering of modern Russian, sometimes mathematics as far as multiplication and division,--this is the state education of the privileged few of the peasants’ children. Whatever small amount of real knowledge is gained is quickly submerged in the ocean of ignorance at home. The percentage of illiteracy is very great. The record gives Switzerland five, Germany seven, Great Britain ten, France fifteen, Russia eighty-four.

It is argued that for the bulk of the population, under existing material conditions, schools are of small use. The lack, in the general poverty, of the very primary materials,--paper, pencils, books; of proper shoes and clothes; the unsuitableness of the houses of the peasants as places for the children to prepare their lessons in, with no spot to put their books or to do their tasks and with no available light--all these things strike at the very root of education. The population must be raised economically to the point where the elementals of existence are assured, before the incidental costs of schools can be met by the peasantry. However, there has been coming to Russia during the last generation, in a great wave, the kind of education that made the American West--the education of expansion, of the founding of towns, the planting of new industries, the building of new railroads, the opening of better navigation-routes, the enlistment of foreign capital; all the intelligence and enlightenment that attends a real industrial, commercial, and material quickening.

Beyond these social and economic factors a large count is set against the bureaucratic system for the conduct of administration. The suppression of personal liberty, of freedom of speech, the abuse of power by arbitrary officials, remorseless repression, ruthlessly carried out, racial oppression, frightful cruelty in the prisons and exile stations;--it is a terrible indictment that has been drawn. The close of the Japanese War opened a new “Smutnoe Vremya,” or time of trouble. Industrial wars, riots in Baku, uprisings in the Caucasus, seizure of cities by Social Democrats,--so went the disturbances throughout Russia, the white terror above grappling with the red terror beneath.

The situation which the forces of order were required to meet was extraordinary. The balance-wheel of the human mind, and all sense of proportion among classes of the people, seemed at times to be lost. Barbaric as the administration condemnations undoubtedly were, the individuals were not infrequently innocent only by curious standards. In a broad view one must confess that on both sides were rights and wrongs. The system, far more than individuals, was at fault. But while a system so linked to violence and oppression could not longer be suffered, the way out could not come through yielding to men in insurrection.

Salvation lay along the path that the Emperor opened. His rescript of October 17, 1905, proclaimed a National Duma.

The pregnant clauses in the summons to a national legislature were these:--

We direct the Government to carry out our inflexible will in the following manner:--

1. To grant the population the immutable foundation of civic liberty based on real inviolability of the person and freedom of conscience, speech, union, and association.

2. To call to participation in the Duma those classes of the population now completely deprived of electoral rights.

3. To establish it as an immutable rule that no law can come into force without the approval of the State Duma.

The ebullition of sentiment that followed these decrees was extraordinary. All the bitterness and discontent that had weltered through the years of distress were metamorphosed into a glowing hope. Ambition and aspiration became a fervor. The delirium went electrically through all classes during the few following weeks of uncensored press and unfettered meetings. The educated

were fed with every sort of essay upon what would be the result of the new order, and exhortation to keep spread the young wings for national ascension. Among the unlettered peasants, pictures circulated showing glorified cartoons of the risen Russia. One of the most widely distributed of these celebrated the Imperial Svoboda Manifesto. The genius of the Slav stood forth: one hand rested on a tablet marked “Zakon” (Law), the other unfurled a banner inscribed in blazing red letters, “Svoboda” (Liberty), below which followed freedom of speech, of forming associations, of holding meetings, of religion, the inviolability of the home, and amnesty for political prisoners. Peasants and workmen were grouped around, and above them stood an heroic figure representing the Duma which was to halo all national activity with law. The rising sun, illumining the Tauride Palace, cast its glow and glamour over the prophecy.

The ukase had gone forth to give the widest representation at the polls. The command was followed out in a system by which every class had its own deputies in the nominating colleges that elected the Duma members. Among the peasantry each _volost_ had two deputies; every thousand industrials had one, the nobility, the salaried clerks, the bourgeois in the cities, the Cossack stanitzas, the boards of trade, the universities, the Holy Synod, the aboriginal Buriat tribesmen,--each had special representation. Uninterfered with for the most part by officialdom, all Russia crowded to the polls, every man believing that his ideal was now, at last, on the eve of realization. The peasants who called for land, the workmen who wished for higher wages, the Intellectuals with their slogan of universal education, the submerged races with dreams of reborn nationalities, the ambitious with visions of power, the venal with hopes of plunder, each and all thought their hopes were to spring at once into the actual and the visual.

In such a fever-time the men to whom official service meant the slow toilsome improvement of conditions by self-sacrificing devotion to the routine of administration, who could offer as pre-nomination pledges only earnest study and conscientious action on the legal matters presented, were passed by in the hot aspiring canvass for delegates. Those who believed all things and promised all things, whose fervency of expectation fed the universal hope, whose preaching held that, the way once cleared, Russia could at a bound reach the plane to which other countries had so long and toilsomely struggled, those of fiery faith which would consume every obstacle--these were the men whom the people ratified and whom the nation sent to St. Petersburg for the first Duma.

It was a band of hot heads and eager hearts that assembled, echoing their constituents’ desires, crying for all things and at once. They were saturated with the history of the French Revolution, they felt confident that their coming meant the end of the old régime, and belief in their own power was the pledge of the future. Their first official act threw down the gauntlet to autocracy. In the reply to the Crown, passed during their first day’s session, the final paragraphs read:--

The most numerous part of the population, the hard-working peasants, impatiently await the satisfaction of their acute want of land; and the first Russian State Duma would be recreant in its duty were it to fail to establish a law to meet this primary want by resorting to the use of lands belonging to the State, the Crown, the Royal family, all monastic and state lands, also private landed property, on the principles of eminent domain.

The spiritual union of Russia’s different nationalities is possible only by meeting the needs of each one of them, and by preserving and developing their national characteristics. The Duma will try to satisfy these wants.

Sirs, the Duma expects of you full political amnesty, as the first pledge of mutual understanding and mutual agreement between the Czar and his people.

It was apparent that if these clauses did not contemplate the confiscation of private property, which was openly advocated by the peasant deputies, and the substitution of a “spiritual union” of Russia’s subsidiary peoples for the real hegemony, there was fair _prima-facie_ evidence for thinking that they did. While a general amnesty would render less than justice to a large number of citizens, it would cover as well the bomb-shell anarchists, whose imprisonment was as necessary to the protection of society as that of any other dangerous criminals. The tenor of these demands, the speeches of the deputies, and the avowed desires of their majority, brought matters to a crisis. Not alone the autocracy, but national unity, and the jurisdiction of the courts, were called openly and violently into question. When such a challenge is offered a government, it must answer or abdicate.

Unostentatiously, the Imperial Administration poured troops into St. Petersburg from Kronstadt and the northern garrisons. The governors at Moscow, Odessa, Warsaw, and the big industrial centres were notified to concentrate their loyal regiments. The whole country was mapped out like a checker-board. It was now only a question of when the authorities would act.

On the night of July 8, the troops in St. Petersburg were called to arms. They marched with machine-like precision to appointed stations throughout the city. With the dawn every strategic point was held by the soldiery, and a battalion ringed about the deserted

Duma hall. In the silence was read the imperial rescript. The first Duma had ceased to exist.

The dissolution of this national parliament had come as a stroke of lightning. The venerable representative Petrunkevitch told how he was awakened at five in the morning with the news that the city was under martial law and that soldiers with fixed bayonets were at the Duma doors. Hurried consultations were held with groups of colleagues, and finally the word was passed to meet at Viborg in Finland. At the little inn there, the pressing crowd of one hundred and sixty-nine fugitive deputies signed their manifesto. It called for the cessation of tax-payments, the refusal of conscription, and reclaimed the freedom of Russia. But the insurrection, the uprising in their support! Not a regiment came to assist them, not a city rallied to their call, not a Mir responded. For a few weeks the signers were free. Then the police took them, one by one.

Dully unprotesting, the public received the news of the dissolution of the Duma and the arrest of the deputies. The majority of Russians did not want disunion, did not want the overthrow of vested rights. Each wanted some specialty of his own. Yet here was the resultant of each constituency's crystallized desires. The people had accepted the leadership of those who had held out great hopes, impotently. The Government had crushed the men whose power meant social and economic, as well as administrative, revolution. In the blow it had perforce shattered the dreams as well.

[Illustration: THE TVERSKAIA GATE LOUBIANSKAIA PLACE STREET SCENES IN MOSCOW]

Humiliated by the contemptuous condemnation of their chosen representatives, bitterly disillusioned, the people at large stolidly acquiesced in the extinction.

The voting for the second Duma, which followed some months later, was almost perfunctory. Those who had chronically wished to agitate, and those put forward by the Administration in an effort to pack the membership, composed the bulk of the deputies. Moderates, hopeful of progress with order, stayed at home, disgusted with both sides. The result was a second violent, wrangling Duma, offending like the first, and in its turn ignominiously snuffed out.

The year 1907 saw universal disappointment, cynicism, and skepticism. In the literature, the lassitude of the nation was shown, and morbid despair reflected the thwarted hopes, the agonies, the confusion of the people. The bitterness in the _Lazarus_ of Andreyev, the decadence in the _Sanin_ of Artzybashev, mirrored the people's mood, and the shadow of a dark destiny brooded over all. To fill the cup, the reaction, coldly triumphant, was able to bring the members of the first national parliament before the bar for high treason in signing the Viborg Manifesto.

In the stifling Hall of Justice in St. Petersburg, like a resurrection of the first Duma, sat the hundred and sixty-nine signers, grouped as of old by party affiliations. Each man was called upon to justify his actions. Many had signed the Viborg document in the belief that the people would rise in bloody rebellion, and they issued what was, to their fevered view, advice of moderation. One deputy after another stood erect to answer for his deeds. If the men had been carried from liberty into license, at least they had been fired by intense belief in themselves and in their mission. Impressive were the solemn declarations of those who expected nothing less than long imprisonment for speaking out, now, a defiance to the ruling power. It was currently rumored that should the former President of the Duma, Dolgoroukov, justify his action, his penalty was to be three years' imprisonment; the others would serve one; while liberty was reported to be the bribe for any who would confess a fault. Yet almost to a man these old deputies rose to declare that they still stood by all that they had done.

"I did not care, and do not care if our action was unconstitutional. We found that we must rely," said Nabokov, "on the highest law, the will of the people."

Kakoshtin, of the Cadet Party, and a professor in Moscow University, declared: "Whatever fate awaits us, it will be nothing compared to the sufferings of our predecessors who have fallen in the fight for liberty."

Three members of the "Group of Toil" declared that the first Duma would be an encouragement to the people to overthrow the present system.

Mourontzev, and Prince Dolgoroukov were there, leading members of the first Duma. Petrunkevitch ended his speech: "If you open for us the doors of the prison, we will quietly enter with the knowledge that we have fulfilled a duty to the Fatherland."

Burning words these, but they waked not an echo. The Administration was in complete control of the situation. Repression was the order of the day, repression as widespread and efficient as in the days of Nicholas I; the autocracy, buttressed by an army which, however lacking in discipline and supposedly honeycombed by disaffection, nevertheless rallied still to the command and service of

the master.

At this time there was issued the call for a third Duma. As Prime Minister sat cold Stolypin, whose reputation as a governor-general was the reverse of liberal. He had risen by virtue of rigid efficiency. His best friends did not know his beliefs. He had dissolved both the first and second assemblies, and had done his best to pack the third. “I want a Duma that will work, not talk,” he declared.

The murmurers said that the Russian Parliament had become a farce; that the administrative officers were following to the best of their ability instructions from St. Petersburg to deliver a roster of safe men; that those who had agitated unwisely were being removed from the likelihood of candidature; that the Senate, with its membership of retired officials, had so construed each provision of the election law that the unquiet classes were as far as possible disfranchised; that every influence was being used to make the third a “dummy Duma,” hopelessly manipulated into the reactionary camp.

Throughout this time of shattered ideals and discouragement, a very small band of real believers still held high the torch of faith. Most prominent among them was Alexander Goutchkov, he who among the Moscow Constitutional Democrats (the “Cadets” of the earlier times) had in a critical Polish debate of the party spoken and voted alone for a united Russia.

When at length the third Duma had assembled, the so-called Octobrists or Moderates, who had a small plurality, prepared a reply to the Speech from the Throne. Very respectful it was, with no demand for general amnesty or suggestions of confiscation or national devolution. It read in part:--

We wish to devote all our ability, knowledge, and experience to strengthening the form of government which was given new life by the Imperial will; to pacify the Fatherland, to assure respect for the laws, to be a buttress for the greatness and power of indivisible Russia.

Unexceptionable, this, to the higher powers, save that in the preamble in the original draft, the Czar’s historic title of “Autocrat” had not been given him. A debate followed, and brought about the declarations which defined the parties of the third Duma. Bishop Mitrophane, of the Right, or reactionary party, rose. He said in the name of his group that the Address to the Throne must contain the phrase “Autocrat of all the Russias.” Lawyer Plevako seconded, threatening to secede if the proper title were not incorporated. Paul Milyoukov spoke hotly for the opposing Cadets, asking whether the country was or was not under a constitution. He declared the new election law to be contrary to the original ukase and an act of force. Others of the Left, among them orator Maklakov of the Cadets, declaimed against the election law by which this Duma was constituted. They were not politic, these spokesmen, but harsh and dogmatic, yielding none of the courtier-respect that makes up for so much absence of real yielding. For the Octobrists, Alexander Goutchkov led the debate. His speech revealed that they operated, not with the bludgeon, but with the Damascus blade. They were of flexible obstinacy and opportunism, stirring up no sleeping dogs, bending to rise again. Goutchkov slipped adroitly into his speech the disputed word constitution, thus: “We do not believe that the Czar’s power has been diminished. The Emperor has become free, for the Constitution has delivered him from court camarillas and the hierarchy of chinovniks.” Thanks largely to his tact, the Octo brists won. The Address, without “Autocrat,” was passed by a vote of two to one. But it passed at the cost of self-separation by the right wing of the reactionaries, who withdrew.

The answer of the Administration came sharply from Prime Minister Stolypin:--

The manifesto of imperial power has borne witness at all times to the people that the autocratic power, created by history and the free will of the monarch, constitutes the most precious benefit of the political state of Russia; for it is this power and this free will that are alone capable, as the tutelary source of existing constitutions, of saving Russia in times of trouble, of guaranteeing the state from the dangers that threaten it, and of bringing back the country to the way of order and historic truth.

He called upon the Chamber to incorporate the recognition of the “Autocracy.”

A hundred members protested. Many of the Cadets walked out. To the Octobrists, barely a quorum, fell the humiliating duty of recalling their own address and of inserting, despite the scorn, the fateful word. So shaken was the group itself by the conflict that of its one hundred and sixty members but ninety-five united in the caucus that elected officers and committee members. Alexander Goutchkov was chosen chairman, Baron Meyendorf, Priest Bjeloussov, and Radsjauko, officers. Among the heads of committees were Prince Wollanski, and Peasant Kusovkov. In spite of the stigma of reaction popularly imposed upon them, these were not unrepresentative men.

The distracted Duma got slowly under way, and the Prime Minister brought before them his proposed policy of administration.

M. Stolypin’s address to the Duma, November 16, 1907, stated that:--

1. The destructive movements of the party of the extreme Left have resulted in brigandage and anarchy. Order will be the first duty of the Government.

2. Agrarian relief is the first necessity, and this by a system of small proprietors.

3. Local self-government and administrative reforms will be formulated and presented to the Duma.

Business got centred on these practical subjects. Discussions as to whether or not there was an autocracy gave place to famine-relief measures and railway-rate studies. The absenting delegates of the Left and Right, who had retreated to their tents in the wrangle over the Czar’s titles, and had left the forlorn little band of constructive Octobrists to carry on the work of legislation, now returned. The proceedings began to take parliamentary form.

The Budget came on, the Ministers of the Government presenting their projects for discussion. In the heat of debate, the Minister of Finance, M. Kakovtsev, exclaimed, “Thank God, we have no parliament yet!” The fact that an Imperial Minister was presenting his budget to an elected assembly showed the reality, but the war on names rose up afresh. The Duma officially declared the Minister’s expression unfortunate. He threatened to resign unless the house apologized. The Left again exploded in outcries, called out that the Duma was a farce, threw in their votes as more fuel for the flame of discord, and deserted the hall when they were in the minority. Still the little band of moderates chose the self-abnegating, unspectacular part, and gave the apology that avoided a crisis.

But now came up a matter wherein the dispute was not over a name or a title, but a reality. The Government, upheld by the Czar, the Court, and much public sympathy, proposed a programme for a new navy. It called for the immediate allocation of one hundred and eleven million roubles, and the expenditure in ten years, of over a billion roubles. In the state of the country this entailed a fearful burden, perhaps the loss of the gold standard. The outwardly supine members, in rows like grenadiers, voted against the project. By 194 to 78 it was lost.

The Minister of Finance shortly afterwards undertook to issue railway bonds without the Duma’s consent. With a rebuke, for which this time no apology was asked or given, his estimate was cut down by one rouble, and voted. The Amur Railway was authorized, though three hundred million roubles are its prospective toll. The sole remaining Pacific port of Russia, Vladivostok, is thereby linked with the Irkutsk and Trans-Baikal districts of Siberia, and so doubly insured against an eastern enemy.

After a lengthy session the third Duma adjourned, but not by violence. It could show as results two hundred bills passed, a budget thoroughly scrutinized and ratified, and much faithful work in committee. More important still, the Parliament, by forbearance and patience, had made itself a part of the machinery of government, and had shown that a national legislature did not mean expropriation, and a partitioned Russia.

At the end, fiery Maklakov of the Cadets, he who early in the session had cried out that all was a farce, admitted that “the third Duma has lost none of its rights, it is systematically extending them.” All honor to those whose self-suppression and patience won.

The thin edge of the wedge had been driven in under absolutism by the third Duma, but little could one foresee that a half-dozen quiet blows would, during the fourth Duma’s session, bring autocracy to the greatest crisis it has encountered since it decreed a legislature. The heart of the situation lies in a naval bill submitting to the Duma matters which the Constitution reserves to the control of the Emperor. Strangely, too, the Czar is himself the abettor, if not the originator, of the supplanting.

In May, 1906, the Czar decided to create the “Naval General Staff.” One hundred thousand roubles a year were needed, and the money must be sought of the Duma. The first two assemblies being so violent, the measure lay in abeyance, to the great injury of the service. Since the regeneration of the navy was one of the measures made painfully necessary by the Japanese War, M. Stolypin had a bill drafted, in three clauses: one ratifying the creation of the “Naval General Staff,” a second furnishing an annual sum for its operation, a third supplying a fund for contingencies. No feature of the creation, save the financial aspect, came at all within the legal jurisdiction of the Duma. Yet the Premier had the organization itself brought before the Assembly.

The deputies criticised the institution, modified it, sliced the estimates. Assuming the judicial functions of a court of last appeal, they voted the money and passed the bill, which M. Stolypin then submitted to the upper chamber. In view of the overstepping of domain, the bill was, after a lucid exposition of the law by the ex-Controller-General, thrown out.

The matter was next submitted to the Czar himself, who authorized its reintroduction in the Duma. A second time the measure was passed and sent to the Council. M. Durnovo, ex-Minister, ablest of the Conservatives, and candidate for the Premiership, made a notable speech. He proved clearly the trespass upon the rights reserved to the Crown, showed that such precedents would build up an artificial claim which could not later be combated, while the allowance of participation in one instance gave a warrant for demanding interference in any and every proposal. The bill was a blow at the very heart of monarchical government, and a degree of democracy not allowed even in republican France. But, defiantly, M. Stolypin held his ground. The anomaly was presented of Conservatives decrying the Premier for undermining the dynasty, with the Emperor himself supporting the culprit. Thus has the former government minority been converted into a majority,--the measure passed by the small margin of twelve.

The reactionaries have bitter feud with this Premier. He has, it is allowed, so enlarged the functions of the deputies by handing over to them, one after another, the vital prerogatives of the autocracy, that no later action can ever disestablish the Duma. The Empire is now governed through a unified cabinet; the important prerogative of appointing the governors-general has been exercised by the Premier, rather than by the Czar, since June 16, 1906. Russia has marched far on its upward way.

Great, however, is the task ahead. Of all that the Duma can achieve the country has supreme need. The agrarian question calls aloud for solution, and the peasants' future depends on land-relief. The Emperor has given instructions for the sale of most of the Crown domains and those of the Imperial Family. The nobles are being encouraged to sell to the tenants, on notes guaranteed by the Imperial land bank. Firm and able hands must guide this improvement, promoting the division of estates left to run wild, but avoiding the pitfalls of threatened property-rights.

Individual enterprise must be awakened, which will in the end bring about more scientific rotation and intensive farming. The old system leaves fallow thirty-three per cent of the arable land--an area equal to the whole ploughed acreage of the United States. In western Europe but seven per cent is fallow, and the value of the harvest per acre in Russia is less than a third that of Germany. The policy adopted in the Agrarian Law of November 9, 1906, for the gradual breaking-up of the communistic Mirs, and the division of the common lands, at the villagers' option, into freehold plots, is a wise one. In 1907, the year following the law's promulgation, 2617 peasants, in the government of Ekaterinoslav had become individual proprietors. Under the Land Act of 1909 one million farms had been taken up for private ownership in the first six months of the law's operation.

Emigration to the vast untilled fields of Siberia should be carried on with all the efficiency of which the Government is capable. That this is in progress, the figure of four hundred and ninety-one thousand emigrants for the first seven months of 1908 attests. Fifty-nine thousand homeseekers were sent by villages which wished to emigrate thither _en masse_. But care and providence must follow the movement, and insure that the settlers are equipped with the means for safe and permanent establishment.

The race-question calls also for a righteous solution. The future must bring the repeal of the old bureaucratic laws of Jewish exclusion, and end the vicious circle of oppression and terrorism against this much wronged people. The chaotic finances of the Empire must be regulated by years of patient work, such as that of the last Duma, through whose agency there is now, for the first time in twenty-two years, a budget surplus.

The Duma members, to whom these all-important tasks fall, must plough the fields in all their armor. The autocracy is not their greatest enemy. The history of parliamentary government demonstrates again and again that in an ordered community authority gradually reverts to the national representative assembly. Little by little power slips away from the throne. In England, in 1686, the reign of James II could show Jeffreys' Bloody Assizes; yet five years later the Parliament was in full and permanent control of the government.

The preservation of the country from the nether chaos is, however, a mightier problem. Before the ship of state rides safe in the harbor of true representative government there must come a critical period when the administrative powers are not firmly clasped by the hand of either autocracy or duma. This hiatus-time, when iron repression ceases and sober self-rule begins, is yet to come. Those who must tide the nation over it are such as those pathetically few Octobrists, unpopular because of their bending, craven-seeming policy, and because of the unfree elections that gave them place. Will such a group, when the crucial hour strikes, be allowed peaceably to pilot the vessel? Or will red-handed revolution wrench from their grip the tiller, bereft of the guidance of autocracy? Is it to be evolution or revolution?

One cannot deny that a free election to-day would throw out the toiling Octobrists and put in a membership like that of the first Duma. These constructive, unvisionary men are not loved, nor is their progress likely to make them so. They exist as the ruling factor only by virtue of election manipulations and legal interpretations. With this essentially temporary support taken away, the

group would be powerless, for every indication shows that the people would not support them or their policies.

[Illustration: PEDDLER POLICEMAN RUSSIAN TYPES]

Even Moscow, their former stronghold, fell away in the 1909 elections. There is throughout the country an undercurrent of fierce demand for an immediate millennium, with Liberty as the guiding grace and some particular party as its escort. A song that has become almost an anthem, “Spurn with us that ancient tyrant,” chanted softly by the school-boys to the tune of the _Marseillaise_,--this tells the tale of what is in the air, and in the blood of the people. The most poorly-suppressed desire is insatiate to hack away with one blow the abuses that have, through the centuries, rooted themselves deep in Russian society. The experience of the various revolutionary and terrorist movements proves that their votaries are capable of daring any death for their creeds, and of swimming to their imaged goal in a sea of blood. Let the conservative Octobrist group once succeed in concentrating power in the Duma, and then let a free election substitute for them such men as were in the first Duma, and the Russian Revolution has become a fact.

It is a commonplace to compare the situation with that of France in 1790. There is, however, one fundamental difference. France possessed a numerous and economically powerful bourgeoisie, from whom political rights had been withheld. This class included many strong men moved to a unity of political desire. They were able in the first place to work up into a place of dominance. After the interval of supplanting terrorism, they retook by their own efforts the power which, save for the periods of despotic militarism, they have since maintained. In Russia the conservative middle-class is numerically very weak, and its representatives are unable to seize and hold control themselves. They possess it now only precariously, by the external propping of weakening absolutism. Will Russia’s Octobrists, after performing the function of filching power from the autocracy, meet, at the hands of a new Robespierre, the fate of the high-idealed Gironde?

One cannot yet answer. But whatever the harvest, the work of the third and fourth Dumas, carried out in harmony with the Imperial Ministers, has shown that the last dread arbitrament of social war need not come. Revolution is the final recourse, to be undertaken only if a political and social situation is so desperate that all other means must fail. Such is not the case in Russia. There are administrative abuses there. But governmental restrictions press rather less than one might imagine upon the plain workaday people; and compared to those of other nations, they are not exceptional save in degree. It is the educated and so-called upper classes who complain. Taxes elsewhere than in Russia are burdensome and sure as death. Emigration to Siberia will give any peasant the legal privilege of escaping taxation, which in America is the prerogative of her absentee plutocracy alone. The exile system, dwindling for years past, has now been in effect abolished by the refusal of the Duma to make an appropriation for its continuance. The press-censorship is only the open operation of influences tacitly accepted elsewhere--such as in the United States left the Tweed Ring so long uncriticised. The much-condemned passport is actually of no more inconvenience than showing a railway ticket, and it does not come within “forty _sagenes_” of the custom-house inquisition which faces every American citizen on his return home.

It is not an error to say that in many matters of individual liberty the Slav enjoys more than the American. In the treatment of subject nations, reliable and neutral witnesses declare that Russia does not approach the rigor of the Prussian bureaucracy in Alsace. Many of the Empire’s restrictions are those which obtained throughout Europe fifty years ago--abuses common to a certain stage of civilization, and of public opinion. These melt away in newer customs, for time is curing much. Once the chariot of progress is started, many evils right themselves in the natural and inevitable upward pressure, and many slough off unnoted. It is not so many years back that in America a black man could be deported to malarial lowlands more deadly than Siberia’s steppes; not so long ago that the English Parliament passed an act requiring all railway-trains to be preceded by a man carrying a red flag. Like the seignorial rights of Germany’s feudal states, anachronisms become outgrown, and fall away.

In Russia, unfortunately, the onslaught against iniquitous human laws is overcarried into a blind charge against Nature’s laws, which no revolution can repeal. The protest against dire artificial abuses is mixed with a rebellion against the curse of Adam. It is the fearful fact of life that the destiny of the majority is anxiety, dependence for daily bread on other men, grinding incessant toil remunerated by a bare livelihood, a barring-back from the fullest personal capacity and possibilities through poverty, parentage, environment, and lack of opportunity. The forces of Nature and primal competition put so many limitations upon every one’s action that it is hard to say which are due to the tyranny of men, which are the handicaps born of the nature of things. The cry for deliverance is rising equally in the workhouses of Scotland, in France, where thirty-five per cent of the land is owned by great proprietors, in the slums of New York City, and in the rice-fields of Japan. A government under the present system can but do its best to develop men’s capacities, and to give them a fair deal. All that the best of modern societies has succeeded yet in securing

to the mass of mankind is the chance to get their sons the education which will enable them to vanquish some of the limitations, security for the person, and protection from robbery of the cruder sort.

Capacity and opportunity can come but by slow degrees. When one sees the numbers and the types in the villages, men of latent capacities undoubtedly, but swamped by the spirit of _nietchevo_ and with all their enterprise sapped in the stagnant communism of the Mir, he realizes the futility of a sudden change and the hopelessness of germinating by political pellet the leaven of progress in the hundred and forty millions.

Rulers may be changed by revolution. But the real quickening of the people to their great future must come and is coming by the slow, sure way of evolution.

VIII

THE STORY OF THE HORDES

Among people so peaceful and subdued as are the latter-day Mongols, it is hard to realize that the race has had a past which in tradition at least goes back to the infancy of history. According to legend, the Chinese, the first reputed offspring of the Mongols, preceded by three hundred years Egypt's earliest dynasty. They antedate Abraham's assigned epoch by twenty-six generations. They claim to have continued before Marathon a longer time than has elapsed from the foundation of Rome to our own era. Yet they yield not even to the Romans preëminence of arms, for they won and ruled an empire in extent and population the greatest that has ever existed. Mongols have led the world's mightiest armies; their hosts have carried the ox-hide banners over every great European state but Spain and England, and into every Asian country except Japan.

That the march of Mongols down the long way of history has been so little appreciated is the sword's obeisance to the pen. Save for the mendacious memoirs of Tamerlane, and a few Ouighour inscriptions in Central Asia, chronicles there are virtually none. So story has found a peg for the clipped tails of Alcibiades' dogs, but scarcely a word for the deeds of those who won the world from the Yellow Sea to the Baltic, from the Persian Gulf to the Arctic. Only where the annals of the race have been written in the blood of the peoples they conquered are the events to be traced; only by assembling the alien and hostile evidences of the encircling nations can one shape the outline of Mongolia's mighty past. History takes from the Confucian Book of Records the story of the earliest emigration to the east; from Herodotus the descent upon Mesopotamia and the struggle with Persia on the west. It gleans from the Chinese archives the doings of the Hiung-nu--the Huns; from the documents of the Byzantine Empire the descent on Europe of the same Mongolian "Scourge of God." It culls from Arab historiographs the facts of the southern conquests of Genghis Khan; from Russian monasteries the tale of the northward march of his lieutenant Batui.

The outlines of Mongolia's career are patched and gathered from her frontier lands, yet silhouetted against the far recesses of time they grow steadily clearer and more colossal.

In the year given by most as 2852 B.C., a tribe, whose earliest folk-lore and traditions point to an origin in the cradle of the Hordes near Urga, was pushing seaward down the valley of the Yellow River. Like the children of Israel, they were in constant conflict with the "barbarian" aborigines. This tribe became in due time the Chinese nation.

Through fifteen hundred years the descendants of the invaders wrought out a dimly comprehended civilization on the banks of the Hoang-ho. Behind the imposing national legend, hallowed by the mist of centuries and focused by images of their five Hero Kings, one may see the fact of strong, brave rulers striving for their people's advance. A real statesman was the original of the demigod Shinnung, "holy husbandman," the introducer of agriculture, in whose honor every spring a furrow is ploughed in the soil of his temple courtyard by the Emperor of China. A father in the flesh was that "Nest-builder" who watched the birds construct their homes, and on that model taught his people to make the wattled and plastered huts one sees to-day. The mystic queller of disastrous inundations, Ta-yu, founder of the house of Hia, was the first hydraulic engineer, the dykes of whose successors embank the treacherous Yellow River. He it was who hung at his door a bell which any of his subjects might ring, to obtain immediate attention, and who would leave his rice to answer a call to secure justice. Kie likewise wears human lineaments, he who made a mountain of meat and a tank of wine, and then, to please a frail companion, had his courtiers eat and drink of them on all fours like cows. There is an historic background to the rising against the tyrant under Shang, who later offered himself as a human sacrifice for rain in time of famine, and a kindred note in the story of Chou-siu, sold to misfortunes by a woman whom he loved and immolating himself in his royal robes when the rebellious vassals were closing in around him.

As the years pass, the histories become clearer and more direct, and the legendary aspect of exploits falls away. The Commentaries of Confucius deal with events as tangible and exact as Luther's Reformation: they give the records of kings, and their daily doings two thousand years before our era.

In 1122 B.C., with Wu-wang of the dynasty of Chu, the Chinese nation emerged as a civilized state. It was organized on a feudal system, not dissimilar to that built up by Japan's powerful Daimios. Under this single dynasty the Celestial Kingdom began a period of 873 years of development, marked by the writings of the great sages. Lao-tse, founder of the Taoist religion, with its watchword of "Tao" (reason), but its quick degeneracy to forms and idol-worship, was the first of the Chinese philosophers in point of time. He was at the zenith of his repute around 530 B.C. He had a young disciple struggling through poverty to an education, "Master Kung," known to us under the Latinized nomenclature of Jesuit missionaries as Confucius.

The youth eagerly conned and meditated upon Lao-tse's abstract speculations; but, unsatisfied, he began the studies and compilations from the ancients which to this day constitute the foundations of Chinese literature, etiquette, religion, ceremonial, and policy of government.

Confucius was at once the world's greatest college professor and its most influential editor. His school instructed three thousand pupils in ethics and etiquette. His writings have influenced more minds than those of any other human individual, and his supremacy is the triumph of uninspired work. His moral tone is lofty,--as witness his "Do not unto another what you would not have done to yourself,"--but his life brought no great new message.

"I am a commentator, not an originator," he said of himself.

Mang-tse, "Master Mang," whom we know as Mencius, followed "Master Kung" by one hundred years, applying, as a practical reformer, to the society of the day, the maxims of his enlightened philosophy, rebuking princes and giving to the Chinese world the last of its classics.

In the glories of the Chu Dynasty, China, the earliest offshoot of the Mongol race, reached its literary and philosophic climax.

In Turan, now called Turkestan, and in Mesopotamia, a western division of the Mongols appears about 640 B.C. It is making an incursion into the declining Empire of Assyria, over which Nebuchadnezzar is soon to rule. Nothing of detail remains, only the record of the devastating inroad over the mountain; but it locates at this date the southwestern frontier of Mongol dominion.

Scythia, north of the Black Sea, reveals them next. The sketch is drawn by the master-pen of the Greek father of history in his description of the expedition of Darius, 506 B.C. "Having neither cities nor forts, they carry their dwellings with them wherever they go," Herodotus writes, describing the nomad foes of the Great King. He relates that they are "accustomed, moreover, one and all of them, to shoot from horseback and to live not by husbandry, but on their cattle."

This was the enemy against whom Darius planned a campaign, whose object was to free from the menace of the Scythians north of the line of advance his prospective expedition for the conquest of Greece. From the bridge of boats over the Hellespont, beside which Miltiades watched, the great Persian marched to the Don River, the nomads always retreating. Darius finally challenged the Scythian king to stand and fight, or to accept him as suzerain. To this message Idonthyrsus replied: "This is my way, Persian. I never fear men or fly from them, nor do I now fly from thee. I only follow my common mode of life in peaceful years. We Scythians have neither towns nor cultivated lands, which might induce us, through fear of being taken or ravaged, to be in any hurry to fight with you. In return for thy calling thyself my lord, I say to thee, 'Go weep!'"

All the Asian steppes were open to the ever-retreating nomads: Darius was obliged to halt. Hereupon, the Scythian prince, understanding how matters stood, dispatched a herald to the Persian camp with presents for the king. They were "a bird, a mouse, a frog, and five arrows."

Darius was at liberty to deduce whatever explanation he chose. He retreated, the Scythians hounding his army on. He found his bridge over the Bosphorus safe, and returned to Persia to prepare the Athenian expedition that ended at Marathon. The Scythians remained: they were left leading their flocks as of old over the unconquerable steppes.

By these echoes of clashings with other nations, the first-known streams of Mongol outflow are dimly followed to the Caucasus Mountains and the Black Sea on the south and west, bounding Scythia; to the Hoang-ho Valley, in which were living the metamorphosed Chinese.

But the rolling hills south of Lake Baikal, the source of the race-stream, still poured out fresh hordes, which periodically overflowed in roving nomad bands, harrying the plainsmen. While the feudal states of China struggled and fought among themselves, now coalescing under the “Wu-pa,” the five dictators, now uniting under a Prince Hwan of Shan-tung into a temporary Chinese Shogunate, there came down upon the fertile lands and populous cities wild horsemen, sparing none, burning, looting, riding away. “The Hiung-nu descended on us,” appears again and again in the history.

At length, about 246 B.C., arose the short but glorious dynasty of Ts’in, under China’s king, Shi-hwang-ti. He was a man of action. He compacted a centralized monarchy from the many princedoms, drove back the nomad Hiung-nu beyond the Yellow River, built the Great Wall, and by his glorious exploits blazoned into Europe’s vocabulary, the word China--Ts’in.

In Sz-ma Ts’ien’s history, a striking incident, revealing the Great Emperor’s limitations, is graphically told.

“Li-se, the councillor, said, ‘Of old, the Empire was divided and troubled. There was nobody who could unite it. Therefore did many lords reign at a time. For this, the readers of books speak of old times to cry down these. They encourage the people to forge calumnies. Your subject proposes that all the official histories be burned. The books not proscribed shall be those of medicine, of divination, of agriculture. If any want to study laws, let them take the office-holders as masters.’”

The decree was “approved.” The old books of annals, the Confucian Commentaries, the Odes and the Rituals, to the suppressed execration of the learned, fed the flames. The literati who protested were warmed, themselves, over the same fires.

But despite Shi-hwang-ti’s signal defeat of the five coalescing tribes, and the eighty-two thousand severed heads; despite the victories in 214 B.C., the Hiung-nu Empire grew in power, until it extended from Corea to Tibet.

The Chinese “Han” Dynasty, even under the peasant-founder, Lin-pang, who had proven himself a thorough soldier, was constantly harried. The loss of the old literature continued to be mourned, which argues some plane of general appreciation. The Minister urged the recall of the Ts’in philosophers and the reproduction of the burned books.

“Why have books?” said the Emperor. “I won the Empire on horseback.”

“Can you keep it on horseback?” the Minister asked.

The literati were eventually recalled. Their support was secured for the throne, and the Hiung-nu were kept back by art as well as by arms.

At the Emperor’s death, his widow, the Dowager Empress Lu, of Borgian repute, was still harder pressed by the nomads. Meteh, the khan of the invading hordes outside the Wall, ventured to send to her a proposal of marriage and tariff-treaty couched in Rabelaisian poetry. “I wish to change what I have for what I have not.” He followed the verses with gifts of camels and carts and steppe ponies. In return his messengers insisted on a tribute of wadded and silk clothes, precious metals and embroidery, grain and yeast, as well as the intoxicating _samshu_. These royal presents and tribute were really a trading of goods, a barter, and citizens of lower rank, in the fairs beside the Wall, were carrying on an equivalent.

More and more oppressive became the demands of the Mongols. A band of beautiful maidens, a very toll of the Minotaur, was exacted yearly. In one of the ancient Chinese poems a princess laments the fate that condemns her to a barbarian husband, a desolate land where raw flesh is to be her food, sour milk her drink, and the felt hut her palace.

In 200 B.C., Sin, King of Han, marched against the Hiung-nu, only to retreat after heavy losses, with a third of his soldiers fingerless from the cold. Again, in 177 B.C., the Hiung-nu broke a treaty and raided across the Wall. A speech of the Emperor, in 162 B.C., is quoted in the Chinese chronicles: “These later times for several years the Hiung-nu have come in a crowd to exercise their ravages on our frontiers.”

In 141 B.C., Nu-ti, the fifth of the House of Han, assembled a great army of one hundred and forty thousand Chinese, and marched against the Confederacy. This army, like that of Darius, penetrated far up into the nomad’s territory. Scarcely a quarter of them returned. But the invasion was not fruitless: the Hiung-nu gave allegiance to China. Later, in 138 B.C., largely to turn the left flank of the Horde, the Chinese advanced into Corea. In 119 B.C. another march to the district north of Tibet turned the nomads’ right flank. At length, in 100 A.D., a more northerly Tatar clan, the Sien-pi, came down on the broken remnants of the Hiung-nu. After thirteen hundred years of power this tribe was destroyed. Of the scattered nomads some remained to unite with their victorious conquerors; some went south to Turkestan; a third group trekked north, and went over the great steppe. Subsequent to 100 A.D., they are found

on the east bank of the Volga, where during two centuries they temporarily disappear from history.

The great Empire of China now existed unmolested by the Hordes, and after a few hard fights ruled Asia as far as the borders of Persia. Its outposts almost met those of the Empire of Rome. Both realms were, about this date, in peace and prosperity. There is even a record of trade between them, the Chinese annals telling of an expedition of King An-tun, or Antoninus, in 166 A.D., to Burmah, from which his factors reached the Middle Kingdom; and of glass, drugs, metals, and game obtained overland by way of Parthia from Ta-ts'in, the Great Empire. Pliny writes of silk, iron, furs, and skins, caravan-brought from China. So moved the two empires until 376 A.D., when Valens the Irresolute reigned in Byzantium. To him came messengers bringing word of great alarm from the Danube. The whole nation of Goths were on the bank, begging a refuge in Roman territory.

"Wild enemies, from where we know not, are upon us!" they cried.

The Goths, who were to subvert the declining empire, were escaping from before the western division of the old Hiung-nu. Valens had the Goths ferried over the Danube, and the Huns established themselves in the vacated places of what is now Austria.

[Illustration: THE MIRACLE OF ATTILA'S REPULSE (From a painting by Raphael in Vatican)]

Amid those hordes arose a leader destined to leave a memory in the sagas of the Scandinavian bards, in the Niebelungenlied of the Teutons, and a lurid trail in the annals of the Cæsars. He called himself a descendant of the great Nimrod, "nurtured in Engaddi, by the grace of God, King of the Huns, the Goths, the Danes, the Medes; the Dread of the World,"--Attila.

A profound politician, he alternately cajoled and threatened the peoples whose conquest he undertook; a true barbarian, no food save flesh and milk passed his lips. He and his men worshiped the mysteriously discovered scimitar of Mars, and from Persia to Gaul, from Finland to the walls of Constantinople, his armies ranged. Ambassadors went from his Court to China. The great battle of Chalons, in which, aided by the Goths, the dwindling forces of Rome's Western Empire won their last victory, alone preserved Europe from his yoke. His descendants, mixing with succeeding conquerors, have remained until this day in the land that is called, after their dreaded name, Hungary.

Back to the history of Sz-ma Ts'ien one must return for the next harvest of Mongolia's dragon-teeth. The Tung-hu, whose descendants are now the skin-clad Tunguses that live far to the north, even up to the Arctic Ocean, came down between 309 and 439 A.D. upon Manchuria. This occupation separated China from Corea, which, thus isolated, preserved for centuries the old Han dialect. The Tung-hu conquerors established a great kingdom extending from the Japan Sea to Turkestan. From 380 to 580 they ruled the northern kingdom of China proper. The leading place among those who composed their empire was held by the tribe of Juju, or Geougen, whose descendants are now the Finns. Subject to the Juju was a Mongol clan descended from the old southern Hiung-nu, who lived hard-by Mount Altai. They were blacksmiths and armorers for the Tung-hu army, and were called Turks. Their crescent power gradually supplanted that of their masters.

In 480 this people appeared on the border of China. By 560 the Turkish Empire had become supreme in Central Asia. They pressed upon the nation of Avars on the Altai borderland of the steppe, until twenty thousand of these, refusing to submit, moved westward. Justinian received the envoys of the fugitives in 558. They offered to serve him, and threatened, if unaccepted, to attack his Eastern Empire. Anxious only to keep them away from his own domains, and indifferent as to which should survive, he sent them to attack his German enemies. The Avars, conquering a place in Europe, established a powerful nation between the Danube and the Elbe, biding their time till with the other barbarians they could descend to the spoil of Rome.

After their rebellious vassals came the Turkish envoys, with richer presents to the Eastern Emperor Justin II, and more alarming menaces. The military alliance of the Turks was accepted and that of the Avars renounced. Kemarchus carried the ratification of Rome's treaty to Mount Altai in Central Asia. For many years there was friendship between Mongol and Byzantine, mutual alliance and trade.

In 618 the great T'ang Dynasty arose in China, whose fame is suggested in the fact that the only Cantonese word for a Chinese nationality is "Man of T'ang." The energetic Li-shi-min subdued the Manchurian Tunguses, and in 630 a great battle broke the Turkish power. China once again was supreme from Corea to the borderland of Persia. During the T'ang Dynasty, Kashmir in India, and Anam were captured by the Chinese.

There followed now a period of centuries when the breeding-place of the Mongol's wolf-born hordes ran barren. In unchronicled obscurity the skin-clad herdsmen lived out their generation. To the feeble Ouighour confederacy fell the sceptre of the steppes. The

old territory of the Hiung-nu khans and the Turkish Supreme King was split into little chief-governed principalities. Manchus and Tung-hus, rallying again, alternately ruled and harried China. Avars and Huns occupied their distant conquests. But in the vast stretch between, the tribes were in a bewitched sleep. The people and the qualities that made the old armies were there; the breed of shaggy ponies which they rode was there; iron reddened the hill-slopes, waiting to be hammered into spears in the Altai forges; China and Europe were as ripe for the spoiling. All that the Mongols needed was a leader.

In a quaint chronicle of the Middle Ages we read of how he came. When the French took Antioch from the Turks, one Can Can ruled over the northern region out of which the Turks had originally come. To the old kindred in this hour of need they sent for aid. Can Can was of the Cathayans, a people dwelling among the mountains. In one of the valley stretches lived the Tayman tribe, who were Nestorians. After Can Can's death a shepherd, who had risen to power among the Taymans, made himself ruler as King John. King John had a brother named Vut. Beyond his pastures some ten or fifteen days' journey was Mongol; the latter described as a poor and beggarly nation, without governor or law save their soothsayings so detestable to the minds of the Nestorians. Adjoining the Mongols were other poor people called Tatars. When King John died without an heir, Vut became greatly enriched. This aroused naturally the cupidity of his needy neighbors. Among the Mongols was a blacksmith named Cyngis. Ingratiating himself with the Tatars, he pointed out that the lack of a governor left both peoples subject to the oppression of the surrounding tribes. He got himself raised to the double chieftainship, secretly collected an army, and broke suddenly upon Vut. Cyngis sent the Tatars ahead now to open his way, and the people everywhere cried in dismay, "Lo, the Tatars come! the Tatars come!"

While the Turks sought aid of their kinsmen for the defense, the French King sent to King John's reputedly Christian kingdom for help to his crusade. But Cyngis "Temugin," the Man, had come. As Genghis Khan he was to open up the vastest empire the world has ever seen.

In 1200 the young Temugin, in a great battle near Urga, defeated Wang Khan, whom modern research, vindicating the basis of truth in the old Friar William de Rubruquis tales, has shown to have been a Tatar prince of the Nestorian Christian faith, King of the Kitai or Cathayans, in all probability the ruler known to the princes of Europe, through his letters to the Roman Pope, as the Christian potentate of the Orient, Prester John.

Wang Khan's skull, encased in silver, graced the conqueror's tent as a first trophy. In 1206, summoning all the Mongol chiefs, Temugin took the title of Genghis Khan, "The Greatest King."

His armies were turned next to the reduction of his own people, the nomad tribes of the Central Asian plains. As one after another was defeated, its warriors were incorporated into his growing army. When all these myriad shepherds and soldiers were gathered in, he directed his march towards China.

The Great Wall was as paper to his host. Ninety cities were taken by storm, never one surrendering. For while to the kindred races which he had conquered, and which furnished further recruits for his armies, Genghis was most merciful and humane, to a foreign foe he was indeed the Wrath of God. Once he was bought off from the invasion; but again he returned to the prey. A way into Peking was opened by means of a mine dug under the walls to the centre of the city; through it a picked body of Mongols entered, marched to the gates, and opened them. The savage host rushed in to sack and slay. For sixty days Peking burned, and five desolated provinces of North China were added to the Mongol Empire.

Mohammed, Sultan of Carizme, who reigned from India to the Persian Gulf, was the next objective for the Mongols. In the field, by valor and numbers, the Khan's troops defeated all the Sultan's armies. The walled towns were besieged and taken, largely through the skill of Chinese engineers. The whole great Persian district was harried after the custom of the Mongols through four years; for hundreds of miles the country was so ruined that to this day the old populousness and prosperity have never been recovered.

The army of one of the Khan's generals marched north into Turkestan, and subduing many Turkish peoples, entered beyond the Caucasus the territory of the Polovtisni, themselves Mongols of an earlier invasion. The conquest of Russia had begun. A Muscovite chronicle of those days illustrates the utter consternation and surprise of the inhabitants at this formidable and sudden incursion: "In those times there came upon us, for our sins, unknown nations. No one could tell their origin, whence they came, or what religion they professed. God alone knew who they were." The people generally believed that the time had come foretold in Revelation when Satan should be let loose with the hosts of "Gog and Magog to gather them together in battle; the number of whom is as the sand of the sea." Indeed, in the old map of Tatary, by Hondius, the territories of these two fabled worthies are carefully outlined in what is now Manchuria.

Despite the Tatarean theory of the Mongols' army, the Russian chivalry gathered to the aid of the Polovtisni, and collected an army by the lower Dnieper. Defiantly they killed the ambassadors whom the Mongols sent. The wrathful nomads advanced into the Crimea near the Sea of Azov. The two hosts met in the fatal battle of Kalka. It was the Crécy of Russian chivalry. Hardly a tenth of the army escaped. Ten thousand of the men of Kiev fell; of the princes, six, of the boyars, seventy, died on the field of battle. Matislaf the Bold alone made front, and he was treacherously betrayed and slain.

The way into southern Russia was now open; yet, after their victory in 1224, the Mongols disappeared as suddenly as they had come. The hordes had been diverted to complete the conquest of China. For thirteen years they were swallowed up by the steppe. The son of Genghis, "Oktai," had succeeded the dead conqueror, and had appointed Batui General of the West.

Again there was heralded an invasion, this time by one of the outlying tribes of Khirgiz on the eastern border. The blow was aimed at the very heart of Russia. The old Slav ballads, or "_bilinî_," tell how Oleg the Handsome fell at Riszan. The Tatars entered and burned Moscow in 1237. Onward into the north rolled their conquest, town after town falling. At the Cross of Ignatius, fifty miles from Novgorod, the torrent turned, and, sparing for the time being the ancient republic, swept to the south.

Against the cradle of the Russian race, the white-walled many-towered city of Kiev, Mangu, the grandson of Genghis, now marched. By multitudes the Tatars carried the walls. Fighting to the end, the last defenders went down in a ring around the tomb of the great Yaroslav.

Russia was prostrate at the feet of the nomads. Her princes became vassals, some to journey as far as the Amur to pay their homage to the Great Khan. Without the Tatar Emperor's letters-patent, no prince could assume his inheritance. When the envoy presented the documents, the nobles had to prostrate themselves and accept them kneeling. Each Russian city gave its tribute, even the still uninvaded Novgorod. Every peasant in Muscovy paid his poll-tax. Indeed, the supremacy of the czars of Moscow, when the Tatar yoke was at length thrown off, was largely due to the wealth which the Romanov family had managed to acquire and to hold during their term as tax-farmers of the Great Khan. Russian troops, supplied as part of the tribute, engaged in the Tatar wars, getting in one instance of record their share of the booty--after the sack of Daghestan. They were drafted on account of their great size and valor into a body-guard for the Mongol Emperor in Peking, corresponding to the Swiss Guard of Louis XVI.

While the conquest of Russia was being consolidated into a permanent Mongol dominion destined to endure for nearly two hundred and fifty years, Batui led his army on into Poland and Bohemia. He took Buda-Pest and devastated the country far and wide. The most alarming accounts preceded him, which are still to be read in the monkish annals of the time. "Anno Domini, 1240, the detestable people of Satan, to wit, an infinite number of Tatars, broke forth like grasshoppers covering the face of the earth, spoiling the eastern confines with fire and sword, ruining cities, cutting up woods, rooting up vineyards, killing the people both of city and country. They are rather monsters than men; clothed with ox-hides, armed with iron plates, in stature thick and short, well-set, strong in body, in war invincible, in labor indefatigable, drinking the blood of their beasts for dainties."

The Holy Roman Emperor, Frederick II, who undertook to gather the powers of Europe to meet the danger, wrote to Henry III of England:--

"A barbarous nation hath lately come called Tatars. We know not of what place or originall. A public destruction hath therefore followed the common desolation of Kingdomes and spoil of the fertile land which that wicked people hath passed through, not sparing sex, age or dignity, and hoping to extinguish the rest of mankind. The general destruction of the world and specially of Christendom calls for speedy help and succour.

"The men are of short stature but square and well-set, rough and courageous, have broad faces, frowning lookes, horrible cries agreeing to their hearts. They are incomparable archers.

"Heartily we adjure your majestie in behalfe of the common necessitie, that with instant care and prudent deliberation, you diligently prepare speedy aide of strong knights and other armed Men-at-arms."

Throughout Europe the dread was universal. In 1248 Pope Innocent IV sent to the Tatars an embassy with money, begging them to cease their ravages. Failing, he summoned Christendom. Louis IX of France prepared a crusade. The fishermen of England could not sell their herrings because their usual customers, the Swedes, had remained at home to defend Scandinavia. Fortunately, the tide of western Mongol invasion had spent itself. After wasting the Danube district, the death of the Great Khan recalled Batui in 1245.

[Illustration: ON THE ROAD TO THE MING TOMBS]

Syrian archives reveal the Mongols' next appearance. In 1243 Hatthon, King of Armenia, sought Mangu Khan at Cambaluc (Peking), praying him to fight the Saracens and recover Jerusalem. Mangu sent his general, who speedily took Antioch, spoiled Aleppo, and sacked the city of Bagdad.

When the latter was stormed, Haloon, the Mongol general, ordered that the Caliph be brought alive into his presence. There had been found in the city a quite surprising booty in treasure and riches. Haloon asked why the Caliph had not used his wealth to levy mercenaries and defend his country. The Caliph replied that he had deemed his own people sufficient to withstand the Mongols. Then the Khan announced that the precious things which had been so cherished would be alone left to the miserable man, who was shut into a chamber with his pearls and gold for sustenance and perished in torments. There was no Caliph of Bagdad after him.

Thus, almost simultaneously, there were conquered by the Mongols, northern China, Syria, Russia, Hungary, and Poland. The stream of human blood that it cost is immeasurable.

Of the first conqueror, Genghis Khan, an Arab poem says:--

On every course he spurred his steed He raised the blood-dyed dust.

The lives of four and a half million people are reckoned as his toll on humanity. He had proposed to raze every city and destroy every farm of the five northern Chinese provinces, to make pasture for his nomads, and was only dissuaded by a minister, who ventured death in opposing him. It was he who ordered the million souls of Herat to slaughter. Batui, subduer of Russia, called "Sein Khan" (the Good King), is said after the Moscow massacre to have received 270,000 right ears. Following his fight with the Teutonic knights, near the Baltic, nine sacks of right ears were laid at his feet. "Vanquished, they ask no favor, and vanquishing, they show no compassion." "The Mongols came, destroyed, burnt, slaughtered, plundered, and departed," summarizes an Arab; and the unimaginative chronicles of the Chinese tell without comment of city after city taken, and their inhabitants put to the sword.

Utter ineradicable barbarity would, on the face of things, seem to have been the inmost nature of this people. Yet only a few years later, when Mangu Khan was ruling at Caracorum, the Court had become civilized. Forty-one years after Genghis Khan's death, when the great Venetian traveler Marco Polo arrived at Kublai's Court, the palaces and the organized statecraft at Peking had become a model of efficiency. The Mongols, not as a race, but in the sphere of their leaders, had become a real nation, not unworthy of its success.

It is interesting to reconstruct the Tatar capital and note its development in half a century. The Minorite monk, sent to beg aid from the supposedly Christian Mangu Khan for the delivery of Jerusalem, wrote a detailed description of the city, Caracorum. It had a circuit of three miles and in dearth of stone was rampiered strongly with earth. It had two main streets: one of the Saracens, where the fairs were held and where many merchants assembled, attracted by the traffic with the Court, and with the continuous procession of visitors and messengers; the second chief street was occupied by Chinese, who were artificers. The town had four gates. In the eastern section grain was sold, in the western sheep and goats, in the southern oxen and wagons, in the northern horses. Beyond were large palaces, the residences of the secretaries. The Khan himself had a great court beside the city rampart, enclosed not by an earth but a brick wall. Inside was a large palace, and a number of long buildings, in which were kept his treasures and stores of supplies.

Twice a year the Khan held high festival, with drinking-bouts whereat Master William, a captive taken in Hungary, served as chief butler, officiating at the tree which he had devised to pour forth intoxication. The ambassador of the Caliph of Bagdad came in state, carried upon a litter between two mules. Before the Khan, rich and poor in multitudes moved in procession, dancing, singing, clapping their hands. The guests brought gifts to the monarch. Those of the ambassador of the Turkish Soldan were especially rich, but for quaintness the Soldan of India scored. He sent eight leopards, and ten hare-hounds taught to sit upon the horses' buttocks as do cheetahs. Manifestly it was no raw encampment of barbarians, this Caracorum of Mangu Khan.

If the Mongol's Court could, in 1253, show this degree of "pomp and pageantry," how much was it exceeded by that of Kublai the Magnificent, visited and told of by Marco Polo.

Kublai had established a second seat at Shang-tu, and had built not merely a court, but a city. His palace was of marble, its rooms aglitter with gold. Art had come, and the ceilings were painted with figures of men and beasts and birds. Trees of all varieties, and

flowers, were executed with such exquisite skill as filled the traveler, familiar with the best products of Italy, with amaze and delight. Sixteen miles of park, enclosed by a wall, embosomed the palace. Rivers, brooks, and luxuriant meadows diversified the landscape, and white stags, fallow deer, gazelles, roebuck, rare squirrels, and every variety of attractive creature, lent gayety and charm.

The Khan rode weekly with his falcons. Sometimes a leopard sat a-croup behind him, and was loosened at the game that struck his fancy.

The tale runs on of the Khan's silk-corded pavilion in the grove, gilt all over, and having lacquered, dragon-pedimented columns; of cave-born rivers running deep below the ground; of treasured gems and gold.

No wonder that Coleridge's imagination was warmed to his dream poem.

In Xanadu did Kublai Khan A stately pleasure dome decree, Where Alph the sacred river ran, Through caverns measureless to man, Down to a sunless sea.

London's tortuous streets were to wait two hundred years for their first pavement, when Cambaluc's were so straight and wide that one could see right along them from end to end, and from one gate to the other. In the Khan's parks, the roads, being all paved and raised two cubits above the surface, never became muddy, nor did the rain lodge on them, but flowed off into the meadows.

In addition to civilization's wealth and magnificence, the Mongols had developed a well-organized government. The Khan's twelve barons exercised his delegated authority, as does a modern cabinet in behalf of the national executive. Cambaluc was policed by a thousand guards. The city wards were laid out, for taxation and government, in squares like a chess-board, and all these plots were assigned to different heads of families. The military roads were constantly kept up by a large force. The Emperor had ordered that all the highways should be planted with great trees a few yards apart. Even the roads through the unpeopled regions were thus planted, and it was the greatest possible solace to travelers.

The post, too, was as thoroughly organized as Napoleon's. The messengers of the Emperor, bound in whatsoever direction from Cambaluc, found, every twenty-five miles of the way, a relay-station. Where the route lay through uninhabited deserts, the relay-posts were made houses of sojourn. At all stations express messengers were in readiness, as links in the system for speeding dispatches to provincial governors or generals: they were equipped with the fastest horses, which stood fresh and saddled, ready for an instant mount. The men wore girdles hung with bells; when within hearing of a station came the sound of jingling and the clatter of hoofs, the next man similarly provided would leap to his horse, take the delivered letter, and be off at full speed. The post covered a full two hundred miles by day, and an equal distance by night. Marco Polo states that, in the season, fruit gathered one morning at the capital, in the evening of the next day reached the Great Khan in Shang-tu--a distance of ten days' journey.

Organized charity was instituted by the Mongol Khan for Cambaluc. A number of the poorest families became his pensioners, receiving regularly wheat and corn sufficient for the year. The nomad levied as tribute a tenth of all wool, silk, hemp, and cloth stuffs, and had therefrom clothing made for the indigent of his capital. He had a banking system, paper money, a wonderful military discipline, advanced astronomy; and he opened the Grand Canal to the commerce of the ages. When one recalls the epoch at which all this existed, and realizes that at that time wolves and robbers disputed mastery of the streets of Paris; that the Saracens were lords of half of Spain; that Wycliffe had not yet published his Bible, and that French was the language of the English law courts,--the advance attained is hardly short of marvelous.

In nothing whatsoever is the Mongol civilization more remarkable and contrasting than in its religious toleration--the last acquisition of a civilized state.

While the Christian King of France was engaged in earning the title of "Saint Louis" by extirpating a people of whose creed he disapproved, his envoy, the friar, came to a country which had attained complete religious liberty and toleration. There were "twelve kinds of idolatries of divers nations." Two churches of Mahomet preached the law of the Koran, and one church of the Christians proclaimed the gospel of the Christ.

He found his own creed treated with especial courtesy, the Great Khan subscribing two thousand marks to rebuild a chapel on the behest of an Armenian monk. He relates that the privilege was accorded to the Church of trying any of their number accused of theft; that the Khan's secretary and his favorite wife were Christians; that a chapel was allowed them within the court enclosure;

and that the Nestorians inhabited fifteen cities of Cathay and had a bishopric there.

Marco Polo found the same indulgent tolerance of his religion. In Calaci, the principal city of Tangus, the inhabitants were “idolaters,” but there were three churches of Nestorian Christians. In the province of Tenduch, formerly the seat of Presbyter John, King George was a Christian and a priest, and most of the people were Christians. They paid tribute to the Great Khan.

Indeed, if the Mongolian attitude toward armed nations combating in Christ’s name has been implacable hostility, toward those of the faith who worshiped peacefully in their midst it has been uniformly tolerant, even favoring. The Nestorians, who brought their creed from Khorassan in the fourth century, had by 500 A.D. bishoprics in Merv, Herat, and Samarcand. The Perait Turkomans as a tribe accepted Christianity, and were unpunished. That the Faith was liberally treated in 781, under the Chinese, is self-acknowledged, on the ancient Nestorian stone of Si-an-fu. Headed by a cross, there is graven in Syrian and Chinese the Imperial decree of 638, ordering a church to be built: it gives an abstract of Christian doctrine, and an account of the “introduction and propagation of the noble law of Ta-t’sin in the Middle Kingdom.” In Si-an-fu at this time there were four thousand foreign families, cut off from return by a northern inroad of fanatical Tibetans into Turkestan.

Another monument of 830, found near the site of the old Ouighour capital on the Orkhon, and carved in Chinese, Turkish, and Ouighour characters, mentions the Western religion. A strange sect of Hebrews of unknown origin found as well an unpersecuted home at K’ai-feng-fu, where the Mosaic rites could be performed. To this day a remnant survives.

The same tolerance for alien faiths marked Tatar rule in Russia. The Khan of Sarai authorized a Greek church and a bishopric in his capital, exempting the monks from his poll-tax. Khan Usbek in 1313 confirmed the privileges of the Church, and punished with death sacrilege against it. Kublai Khan took part regularly in the Easter services, and allowed the Roman missionaries to establish a school in Shang-tu.

Indeed, reviewing the whole sweep of Asia’s religious history, one can hardly escape the deduction that if the greatest race of the greatest continent is idolatrous, it is not the fault of the Mongolians.

The Nestorian missionaries had an unsurpassed opportunity in the fourth century when their faith was new and burning, and the world was at peace. But stigmatized as heretics after a doctrinal dispute which had been settled by the logic of a street fight, in which Cyril’s Egyptian bravos defeated the Syrian henchmen of the Patriarch of Constantinople, their mother church was driven out of the Roman Empire into Persia, where, cut off from the support of the main trunk of fellow Christians, their organization withered away as a lopped branch. The chief congregations in Iran and Turan were overwhelmed by the Mohammedans, until at length there were left only the dwindling congregations in Mongolia, and such communities as those on the Malabar coast in India.

To-day one hears of interesting discoveries. Now it is of the old buried Christian strata among Turkomans of Samarcand, of doctrines preserved through the fury of Islam fanaticism by families that have secretly transmitted Christian worship through the centuries. Next it is of Nestorian monks in Asia Minor, startled at being able to read the characters of Ouighour inscriptions, relics of the writings which their predecessors carried to Mongolia. But for all practical purposes the Nestorian labors, once so promising, are as if they had never been.

Another supreme opportunity for Christianity came when Kublai Khan, in 1268, sent west by the Polo brothers for Roman missionaries to teach his people.

“The Great Khan, ... calling to him the two brethren, desired them for his love to go to the Pope of the Romans, to pray him to send an hundred wise men and learned in the Christian religion unto him, who might show his wise men that the faith of the Christians was to be preferred before all other sects, and was the only way of salvation.

“After this the Prince caused letters to the Pope to be written and gave them to the two brothers. Now the contents of the letters were as follows: He begged that the Pope would send as many as an hundred persons of our Christian faith; intelligent men acquainted with the seven arts, well qualified to prove by force of argument to idolaters and other kind of folk, that the law of Christ was best; and if they would prove this, he and all under him would be Christians.”

In the advance of Christianity the steps ahead have been made not so much by the conversion of the people as by the winning of their rulers,--Constantine, giving to Rome’s legions the standard of the Cross; Clovis; Ethelbert; Vladimir, who drove the whole population of Kiev naked into consecrated water of the Dnieper; Charlemagne, moving against the Saxons with his corps of priests. Where these spoke for a hundred thousand souls, Kublai spoke for a hundred million. He was able to deliver; it was the Pope who

did not rise to the occasion. In all Christendom Gregory could find but two priests to go with the Khan's messengers, and these turned back in the midst of the journey, alarmed by the prospect of its hardships. The Khan, who wished some religion, sent to Tibet, and received the Buddhist missionaries whom he requested. So China, Mongolia, Tibet, and eastern Turkestan are Buddhist to this day.

Yet once again the Christian opportunity came. The way which had been opened into China by Matteo Ricci had been followed by Jesuit missionaries, until at the beginning of the seventeenth century there were two churches in Peking, some three hundred thousand converts in the Empire, and the favor of the Emperor Hang was with the Western faith.

When Christianity was spreading with cumulative rapidity, the Dominicans and Franciscans came in and denounced the Jesuit workers for tolerating the ancestor-cult of the Chinese, and for permitting God to be called "Shang-ti." In vain the Emperor Hang, appealed to by the Jesuits, declared that by "Shang-ti" the Chinese meant "Ruler of the Universe," and that the Confucian rites were family ceremonies and not idolatry. The rival friars persuaded the Pope to proclaim "Tien-chu" the proper Chinese word for God, and to condemn all ancestral ceremonies. Thereupon, the Chinese Emperor, rebuffed and disgusted with all the wrangling fraternities, condemned the Christian religion and killed the friars, save those whom he wanted for the Imperial Observatory.

One cannot but recall an early commentary made by Mangu Khan upon the jarring Christian sects whose rival dogmas have prevented, and do to this day, the common progress.

"We Mongolians believe that there is but one God, through whom we live and die, and we have an upright heart towards Him. That as God hath given unto the hand fingers, so He hath given many ways to men. God hath given the Scriptures to you, and ye Christians keep them not. But He hath given us soothsayers, and we do that which they bid us, and we live in peace."

For some years after Kublai Khan's death, the Mongol Empire held its preëminence by inertia rather than by strength. Each of the khans had his kingdom. Presently the nations that had been subdued began to rise against the numerically small garrisons of Mongolia. In China, the young Bonze, Chu-Yuan-Chang, finally organized a band of Boxers, and succeeded in driving out the last degenerate Mongol khan from Peking. He united the old eighteen provinces and established the Ming Dynasty, the tombs and palaces of whose kings are still the most celebrated structures of China.

In Russia, Dimitri of the Don gathered one hundred and fifty thousand men and defeated the Mongols at Kulikovo.

If the old supreme monarch of the north had lost his sway, in the south the Mongol race was being lifted to its second period of empire under Tamerlane, the Iron Khan. His was the history of the first Mongol conqueror repeated. The ant that Timur watched during his exile, which fell back and returned sixty-nine times before it carried its grain of wheat to the top of the wall, was the symbol of his early career. Constant obscure tribal conflicts, unsuccessful at first, led finally to a gathering of the nomads into a terrible invading army. The Golden Horde was hurled against Dimitri, defeated him, and marched upon Moscow. It was sacked with the horrors of Genghis' days, and all Russia was ravaged to the Don and the Sea of Azov. One of Tamerlane's armies traversed the Pamir into India, and, by the capture of Delhi, opened the way for the Mogul Dynasty of his sons, which was to endure until the Indian Mutiny. His Indian army, returning, swept a swath of desolation through Persia, Mesopotamia, Syria, Georgia, and Armenia. Every city that was taken was sacked, and the event commemorated by a pyramid of skulls embedded in mortar. One hundred and twenty pyramids marked Tamerlane's path through India alone. The Delhi pyramid was made from the skulls of one hundred thousand slain "with the sword of holy war."

Bajazet, Sultan of the Ottoman Turks,--themselves sprung from a nomad Mongol tribe,--was threatened by Tamerlane on the west. In a great battle Bajazet was defeated.

Alhacen, Tamerlane's Arabian secretary, relates that the conquered king was examined by his master.

"Wherefore dost thou use so great cruelty towards men? Dost thou not pardon sex or age?"

Bajazet might logically have responded with a "tu quoque," but his position did not warrant it.

"I am appointed by God to punish tyrants," continued Tamerlane. He had an iron cage made; and locked within it like a linnet, the unfortunate sultan was carried from place to place, because, in the Tatar's naïvely quoted words, "It is necessary that he be made an exemplary punishment to all the cruel of the world, of the just wrath of God against them."

The invasion of China was under way, in 1405, when Tamerlane died, leaving a renewed Mongol Empire, which stretched from the Hoang-ho to the Don, and from Siberia to India.

Here again the descendants of the savage conquerors rose to the requirements of their sovereignty and obeyed the peaceful and humane maxims that each of the two great and warlike and pitiless tyrants had bequeathed to his successors. They ruled with a fair degree of wisdom and a large measure of success. A descendant of Tamerlane was to build at Agra, in 1630, the most splendid monument the world has ever seen, the Taj-Mahal.

In the century after Tamerlane's death the Hordes split up once more, Ivan the Great of Moscow, having consolidated many neighboring princedoms, with the nominal consent of his Tatar overlord, at length seized the opportunity to refuse the payment of tribute. The Mongol Khan had no longer the power to compel it at the sword's point, and without a battle the Tatar supremacy was covertly relinquished. In 1480 the long servitude of Russia to the alien invader was ended. From this time the Mongol nomads appear hardly at all in history. They withdrew gradually to their Asian steppes, leaving in Turkey, in the Crimea, and in India, the kingdoms of their offshoot tribes. Russia and China still felt the raids of the horsemen, for the khans of the Golden Horde were yet not to be despised.

Fernan Hendez Pinto, the shipwrecked Portuguese of the generation after Vasco da Gama, was in China in 1542 when Tatars came down and besieged it. He saw "an emperor called Caran whose seigniorie confineth within the mountains of Gen Halidan, a nation which the naturals call Moscoby, of whom we saw some in this citie [of Tuymican], ruddie, of big stature, with shoes and furred clothes, having some Latin words, but seeming rather, for aught we observed, idolaters than Christians.

"To the ambassador of that Prince Caran, better entertainment was given than to all the rest. He brought with him one hundred and twenty men of his guard, with arrows and gilded quivers, all clothed in chamois-skins, murrie and green. After whom followed twelve men of high giantlike stature, leading great greyhounds, in chains and collars of silver."

When Yermak cleared the way to Sibir, and opened the path that was to lead to the Pacific, the Mongols were pushed south. Russians still had Tatars all along their frontier, but these were pressed steadily back as the Slavic race advanced eastward. The Tatar domains were restricted soon to the steppe country and Mongolia.

After Yermak's time the Mongol power sank. It fell further when the Manchus established their dynasty in Peking in 1644. So low had its estate become that even the old fighting instinct was gone,--all the passionate desire for independence that has been the Mongols' birthright since the dawn of history. How had it vanished? Christianity had not come. Buddhism had come, and it was the tolling of the knell for freedom.

The sum of national energy and the heat of the new dispensation were diverted into theocracy. The meaning of life, its value and its duty, these basic ideas which determine the ultimate activities of every race, were revolutionized by the new faith. To the Pagan the world was good despite its evils; struggle against environment measured the worth of manhood and freedom was the supreme blessing. To the Buddhist, life was an evil in which the soul had become enmeshed. The path to release lay not in overcoming the environment, but in retreating from it within the citadel of the soul. Resignation, self-surrender, the yielding of this world to secure the other world beyond,--such were the forces which transformed the Mongols from the foremost warriors into the priest-ridden, subject, unaspiring people of to-day. The supreme problem in the autonomy of China, and in the subjugation of India, is involved in the point of view of Buddhism and its outgrowth in character.

In 1650 a son of the leader, Tu-she-tu Khan, was made chief of the Mongol _kutukhtus_, or cardinals, with the title of Cheptsun Damba. This monsignor began the Urga hierarchy of Gigins, or god-priests, which has continued until the present time, when the eighth Gigin reigns at the Holy City. As the powerful Tu-she-tu clan lost its vitality, Chinese influence made itself felt. This was directed in general toward the encouragement of the priesthood, whose celibacy and other-worldliness dovetailed with Chinese control.

The Mongol khans, becoming through the years more and more unwarlike, had grown tired of internecine feuds. They were at last won over by China to a nominal allegiance and the payment of a formal tribute, reciprocating which, imperial gifts of tenfold value served as artful bribes. Modestly, diplomatically, came King Stork, leaving to the local Daimios, seemingly undisturbed, their feudal sway. With the coming of the first Manchu governor began the present era of Mongolia.

[Illustration: THE GLORY IS DEPARTED]

As time went on, the Chinese, more astute and cunning, took little by little from the careless hands of the nomad princes the reins of real political power. The native chiefs were wheedled into giving up many ancient rights over the vassals, as well as their general taxing powers. The celibate priests, who were draining the manhood of their idle but powerful hierarchy, were subsidized and directed by the interlopers. They preached to their confiding countrymen obedience and submission. In the Mongol Gigin of Urga, the Chinese raised up a native power superior to all the old feudal lords, whose armies melted away beneath the ecclesiastical dominion. When the Gigin became in turn too great a menace, they caused it to be decreed that each succeeding incarnated Buddha must come from Tibet, and that his main powers must be delegated to a “Council of Lamas.”

In the train of the Manchus came the Chinese traders, polite, supple, calling themselves friends of the Mongols, offering their alluring wares on undefined credit terms which tangled the unsuspicious natives in inextricable usury. Peking-brought gewgaws were paid for a hundred times over in the food and clothing which the natives kept giving to the compounding voracity of the debt.

Chinese coolies pressed up the river-valleys, begging land here, intruding themselves there; more followed, and ever more, until the best of the pastures were filched away, and the nomads, in order to exist, were forced to trek to the more distant and barren slopes. Deforesting transformed into deserts whole provinces. The once famed virtue of the Tatar women is forgotten, and every Chinaman has his “friend” whom he leaves behind when he returns to his native land. The big prosperous Mongol families, that early travelers noted, are no more. Two or three children are the most that one sees to a _yurta_, and the population, owing to lama celibacy and the decreased means of subsistence, is declining from year to year.

This is the people and this the land which sent horde after horde through centuries to conquer the world; where in half a dozen generations a little band of blacksmiths like the Turks could breed a nation that would dominate Asia. With narrowing means of subsistence, and aliens draining their small surplus capital, the Mongol race lies prostrate beneath the Yellow Empire. The grim Malthusian tenet that the world cannot give food for all its children falls short here of the grim actuality. The silent invasion of the Chinese has been as ruthless as was the march of Genghis Khan. The economic garroting of a race is what the world has seen in Mongolia.

No longer are there men to lead or men to fight. Obediently and submissively the once fierce, ranging warriors have yielded to the artfully-imposed yoke. The army of unmatched cavalry has become a memory, and a nation of fighters has become a race of timid herders, with little heart or brain. The sons of the old soldiers have learned to shave their heads and croon Tibetan prayers, and the fires of a people’s ambition are quenched in the creed that makes abstention from effort a cardinal virtue, and annihilation life’s supreme objective. What there was of virtue and of valor lies buried in distant graves. Ringed with the bones of slaughtered captives, rusted swords at their sides, they sleep well, those old forgotten warriors. In poverty and hardship, priest-ridden and debt-ridden, decimated and degenerated, their descendants eke out their sterile days. But there lingers yet among them a half-forgotten memory of the heroic past. The wandering chanter still sings in the twilight the old “Song of Tamerlane”--Tamerlane who will come again, they say, and lead the hordes once more to victory.

When the divine Timur dwelt in our tents, The Mongol Nation was redoubtable and warlike. Its least movements made the earth bend; Its mens’ look froze with fear The ten thousand people upon whom the sun shines. O Divine Timur, will thy great soul soon return? Return, return; we await thee, O Timur!

IX

CHINA

Destiny has bequeathed to his once subject-race the heritage of Genghis Khan, but whether its Manchu possessor can or cannot hold even his own birthright is to-day an enigma. The last few years have seen the gathering of the eagles, disputing the mastery of eastern Asia, where China stands against the world. Slav, Saxon, and Frank press in, upon the supine empire. Has this yellow race the manhood and the capacity to rally against them and retrieve its national integrity?

The cession of Formosa after the war of 1895 began the partition. China’s defenselessness was then visualized. The revelation of her easy defeat set every predatory nation on the alert. Watchful for an occasion, which two murdered missionaries supplied, Germany, by clumsy but successful unscrupulousness, seized Kiao-chow and two hundred miles of hinterland. Three weeks after the bludgeoned ratification of Admiral Diedrich’s grab, Russia procured the signature of the intimidated Emperor to the lease of Port Arthur. France demanded and secured the cession of Kwang-chow-wan, on the mainland opposite the island of Hainan. England acquired the lease of Wei-hai-wei, and continental territory opposite Hong-kong. Italy came to claim as its portion Sanmen Bay; but

this at least China found courage to refuse.

Then followed a period when, backed each by its government, invading cohorts of promoters scooped in franchises and special privileges of every description. The latter part of 1899 saw foreigners pushing in from Manchuria on the north, where Russia with her so-termed railway guards held the strategic route, and from Yun-nan on the south, where France was constructing a similar road of conquest. It showed four European nations so established along the coast that only by courtesy of a foreign government could a Chinese vessel cast anchor in some of the principal ports of China. It saw a Belgian-French railway driving from Peking into the heart of the Empire at Hankow; an American line started north from Canton to the same objective; an English line controlling the territory between the main northern trade-centres, Niu-chwang and Tien-tsin; a French society in possession of a great south-country copper concession; Russians with the exclusive right to all the gold in two _eimucks_ of Mongolia; and an English syndicate deeded the best of the Chinese coal-fields.

The partition was thus far accomplished. The continental nations seemed to be ready for all that they could get. The strength of Great Britain's traditional position, based upon maintaining the integrity of China, was shaken by her lease of Wei-hai-wei, although this lease was to run only so long as Russia should hold Port Arthur. England was on the point of recognizing openly "spheres of influence," as is shown by the inferential claim to special British rights in the Yangtse region set forth in the official transactions of Sir Claude McDonald, and brought out under parliamentary interpellation, when a Secretary of State for Foreign Affairs in the Balfour Ministry spoke of "British rights" to the provinces adjoining the Yangtse River and Ho-nan and Che-kiang.

There was apparently good warrant for the general belief that in expectation of an impending partition a provisional understanding had been reached by the different chancelleries, regarding the share of each nation, England being allotted the mighty domain from the Yellow Sea to Burma and Afghanistan, including all Tibet, as well as six hundred and fifty thousand square miles in China proper. In general, from Shan-tung inland the valley of the Hoang-ho was destined for Germany; the district north of her Anamese possessions for France; all Mongolia and Manchuria for Russia; Corea and the province of Fokien on the mainland opposite Formosa, for Japan. Peking and the surrounding district, whose disposition was embarrassed by jealousy if not by scruples, was alone left for the Chinese.

At this critical juncture, when the day of dismemberment seemed indeed to have arrived, the United States came forward in behalf of the "open-door" doctrine, as a means of preserving the nationality and the integrity of China. In a circular letter to the Powers, our Secretary of State, Mr. John Hay, asked that adhesion be given in writing to three main propositions, appertaining to each country "within its respective sphere, of whatever influence." These points were that no treaty port rights or other vested interests should be interfered with; that the Chinese tariff should be maintained; that no discriminating railway charges or harbor-dues should be imposed.

America's might, thrown into the wavering balance, turned the scale. Great Britain gave ready adhesion. Though the responses of some of the other Powers were evasive, none was at this time willing to bear the onus of an adverse stand: each nation nominally accepted, and the movement toward partition was checked.

To most people Chinese matters seemed settled. The preservation of a nation had been combined with the guaranteeing of a great free market; the orgy of grabbing had ceased. Russia, assenting to the open door, had promised to evacuate Manchuria. The special concessions, though secured by stand-and-deliver methods, it was felt would bring economic improvements and would furnish to the Chinese a demonstration of the beneficent results of Western civilization.

It was recognized that there would be frictions: misunderstandings are inevitable when old ways are faced with new. The extra-territorial rights of foreigners and their converts, absolutely necessary to protect their liberties if not their lives, could not but create occasional unharmonious situations, in which the consuls would have to intervene. The severity of the judicial punishment meted out at times to rioting cities for harm done to the protégés of the Powers was to be deplored, each nation grieving at the atrocities the others had seen fit to perpetrate.

But periodic local and temporary disturbances had been going on from time immemorial. Did not the Chinese realize, we reasoned, that their old corrupt government had been given another undeserved chance to try and march with the rest of the race; that this world is not the place for graft-ridden relics from the fifth century B.C.? The least we felt was that, thanks to the bearer of the "Flowery Banner," the Chinese had been given a last opportunity. A self-denying Occident had guaranteed the nation's existence and had presumably earned its everlasting gratitude. "Let China get up and do something--let it redeem itself."

[Illustration: THE BRIDGE AND TABLETS IN PEI-HAI]

A very small circle of Chinese shared this Western view, and realized at their true value the mights if not the rights. There existed among the literati at Peking and in the coast cities the rudiments of a foreign liberal party. Recognizing that Western methods must come, they had been in favor of accepting foreign improvements even at the cost of railway concessions and the violated dwellings of wind and water spirits. When this party won over the young Emperor, there began the period of foreign concessions. Reforms, too, covering every subject, from queue-cutting to postage-stamps, were inaugurated.

The summer of 1898 saw the important edict which ordered the abolition of the Wen-chang essays and the penmanship posts, with the Emperor's personal comment that the examinations should test "a knowledge of ancient and modern history, and information in regard to the present state of affairs, with special reference to the governments and institutions of the countries of the five great continents, and their arts and sciences." A Bureau of Mines was established, a patent-office, schools, a scheme of army reform.

The climaxing decree was the one abolishing sinecures. For the Emperor's unreconstructed entourage this last was too much. Foreign aggression had embittered to the point of unreason mandarin and coolie alike. The _coup d'état_ planned by the Dowager Empress, and executed by the reactionaries, virtually dethroned the Emperor, exiled his advisers, and ended the foreign-encouragement reform.

Indeed it was not within human nature for it to endure. From the point of view of the party of the second part the aspect of the whole foreign relationship, even after the Hay Note, looked very ugly indeed. The fact of guaranteed integrity was obscured by the _laissez-faire_ of the already consummated grabs. The idea that gripped them was the humiliation of foreign occupation and foreign aggression. It was as if the Russians and the English had just seized rival reservations on Long Island and the Jersey coast, commanding New York City; as if the English had wrenched away Charleston; the Germans, Philadelphia; the French, New Orleans; and Cossacks were garrisoned in strategic points throughout New England. It was as if the New York, New Haven and Hartford Railway were manned and guarded by Slavs, the New York Central by Belgians, the Pennsylvania by Prussians; as if the Pittsburgh mines were handed over _en bloc_ to an English corporation, and the Russians had exclusive mining rights to the gold of Alaska's Yukon region. It was as if America's protective-tariff and contract-labor laws were repealed at foreign dictation, and a flood of foreign machine-made goods and undesired immigrants were poured into the unwilling country. It was as if yellow-robed Buddhist lamas were everywhere haranguing the Yankee farmers, telling them of the fraudulent nature of the Christian creed, and urging upon them an approved canine method for disposing of deceased ancestors, to replace their superstitious funeral services. It was as if astrologers, calling themselves engineers, were to dig up New York cemeteries in order to erect prayer-wheels; as if the apostates whom these yellow priests had drawn into their joss-houses were enabled to dodge part of the taxes, which consequently fell with added oppression on the rest of the people; and as if, when they did something which others would in the normal course of events get punished for, a lama came before the magistrate and got them off. As if the President and the Senate were given a weekly wigging by the diplomatic corps, and were periodically forced to deed away sections of the forest reserve and tracts of particularly desirable territory.

With such an aspect as this, which represents what in an undefined, bewildered way the Chinese saw and felt, it is no wonder that they considered the Confucian dictum obsolete: "Do not unto others, what you would not that they should do unto you"; and joined the patriotic harmonious Fists,--the Boxers.

Chinese sentiment was ungauged in the West because we had never put ourselves in their places. Unforeseen save by a few unheeded Cassandras, and unprepared for, there broke out the planless, leaderless Boxer Rebellion, grim fruitage of the national resentment. A few hastily gathered legation guards were alone available for defense. Spreading from the Shan-tung Province, where the severity of the Germans had goaded the usually peaceable people to madness, the I-Ho-Chuan besieged the legations at Peking. It was the infuriated and ill-directed rush of a patriotism real if futile,--a turning against the spoilers.

The movement was crushed in a torrent of blood, and with a devastation that for long will leave its mark upon the northern provinces. The closing year of the nineteenth century saw the Taku forts stormed, Tien-tsin, the Liverpool of the North, taken over and administered by a foreign board, Manchuria and Mongolia swarming with Cossacks, the Dowager Empress in flight, and her capital looted by foreign armies.

The coming of alien soldiery to the Forbidden Palace left its impress in the fiercer though more carefully smothered hatred of mandarins and people. It was still a blind resentment. They were injured, stung in all their pride and self-sufficiency, but dumb, bewildered, not knowing what to do, which way to turn. The liberals with their solution were gone; with them had passed the hopes

of a progressive policy.

The people, perplexed, looked to their reëstablished reactionary rulers for guidance. But these officials, mostly of advanced age, and steeped in the ideas and ideals of the Confucian classics, were anxious mainly to close the ears and eyes of the masses to the unpleasant realities; to feather their own nests and finish off their lives in tranquility.

The Chinese Minister to the United States, Wu Ting Fang, gives a graphic picture of these Celestial Bourbons:--

“It must be remembered that most of the high officials in Peking are born and bred Chinese of the old school. All the princes and nearly all the ministers of state have spent most of their days within the four walls of the capital. They have never visited even other parts of the empire, not to say foreign lands; nor can they speak any other language besides their own. They have absolutely no knowledge or experience of foreign ways except those who are ministers of the Tsung-li Yamen, and the experience of these men has been confined exclusively to their official intercourse with the foreign representatives at Peking.”

Buttressing their hereditary _intransigeance_, these mandarins had, after the Hay Circular, possessed a measure of confidence that their yielding of open-door trade privileges to the greed of the foreigners had enlisted a combined support which would preserve China’s remaining national powers.

But so powerless to fulfill their purposes had these paper pledges become, so far was the open-door doctrine from settling the situation, that in China’s own territory, where by solemn promises of both parties no special privileges could accrue, the year 1904 saw two Powers in the throes of the greatest war of modern times.

If the realization of the combatants’ purpose has signified much to the nations of the West,--perhaps rather to the United States, for the others nursed no illusions,--to China it has meant far more. It has brought for the first time a real and general appreciation of the necessity for modernized, efficient self-defense.

Fifteen years of aggression have been needed to drive home this knowledge. While the defeats of 1895 came as a blow to a few keen-minded Chinese, to most they were a matter of entire indifference. China was not conquered, they reasoned: only two provinces took part while the viceroys of the rest looked idly on. “That Shan-tung man’s war” was the general attitude; “Li Hung Chang’s boats beaten.” When it was over, merely Formosa, the little-valued island of “tame barbarians,” had been lost. The traditional policy of playing off the jealous powers one against the other had apparently succeeded; it had cleared the Japanese from Corea and Port Arthur. China as a nation was hardly touched, and multitudes of people never knew there had been a war.

The seizures of 1897-1899, coming close upon each other, exasperated, but taught no lesson. The mass of Chinese, and even those in high official circles, believed that a little effort would drive the foreign devils into the sea. The march of the Allies to Peking stunned them. It was their first facing of the fact.

[Illustration: HSUEN-WU GATE, PEKING]

The Russo-Japanese War, and the partition of the province that had cradled their Emperor’s dynasty, dissipated their fool’s paradise. It was seen then, clearly, by all, that China’s only hope of maintaining her integrity lay in her defensive power. With the object, not of securing the blessings of civilization (which the overwhelming majority of Chinamen desire no more than we do the Holy Inquisition), but of beating away the spoilsmen, the Peking rulers turned at length to the survey of their actual military condition. As this concerns intimately the Chinese internal situation, a summary of it may be pertinent.

The Hwai-lien regulars, to the number of twenty-five thousand, are well-drilled, and well-armed with Chinese-made Mausers. They are stationed in the northern provinces, including the Taku and Peht’ang forts, the Tien-tsin station, and the neighborhood of Peking. These make up the only national force of modern troops at the disposal of the Chinese Government, but the private armies of various viceroys bring up the total somewhat as follows: The camps of foreign-drilled troops, formerly Yuan Shi Kai’s, probably the best in China, number roundly twenty thousand. From the Shen-ki Ying, or artillery force, from the camps of the Manchu Banners, which the Government is making an effort to whip into some kind of shape, from the Imperial body-guard, and other scattered and less important troops, ten thousand effectives might be culled. In the south the Viceroy of Nanking has, all told, some twenty thousand more men holding the Wusung forts, who may be classed as efficient and well-armed; some of these are German- and Japanese- drilled. This total of seventy-five thousand represents China’s numerical military strength in effective modern troops.

The old hereditary organization of twenty-four Banners, adds some two hundred thousand Manchus, Mongols, and Chinese,--of the privileged soldier caste, which through two hundred and fifty years has drawn an annual subsidy of eight million taels from the

Peking treasury. Billeted as the nominal wardens of the provincial cities and garrisoned around Peking, these Tatars have become as a rule so degenerated by immemorial idleness as to be useless save for picturesque parades. The one positive element is that they are men under pay, subject to order, and available for initial experiments.

The Green Banner, or militia, under the command of a general for each province, is theoretically composed of a large number of native Chinese. The army is made up mainly of officers. The higher officials of the Green Banner acquire the pay, commissary, and weapon-allotments of their nominal armies, and pad the rolls with the names of coolies who come out for the annual review in return for the small portion of their nominal wage which must be spent to keep face.

To expect these men to get out and fight is obviously more than they bargained for. The Green Banner can deliver about the same relative number of actual soldiers per unit of population that a Mississippi backwoods county polls for the Republican party. The most that can be said for the Green Banner is that it has a list of men's names from which a certain number of real recruits might be obtained.

The military organization of even the best regular troops is feeble. Constant word reaches the press of soldiers revolting for lack of pay. In one such instance nine hundred men near the Manchuria border mutinied and were put down with difficulty, tying up the caravans for some time. Aside from questions of discipline, and considering number only, it is doubtful if, in the whole empire of four hundred million people, one hundred thousand decently armed and drilled troops could be gathered, in an extremity, for defensive purposes.

Drilled and armed men in whatever numbers are, however, but one element of a country's defensive power. Organization, transportation, commissary, and supply are factors of hardly less importance. The troops that get there are the ones which count, and even a Chinese army marches on its belly. Russia's defective transport, to mention but one case, undoubtedly decided both the Crimean and the Japanese wars. The question of territorial defense is one of several dimensions, first of which is how soon could a given force, with its necessary commissary and ammunition-supply, be disposed along the various lines of possible attack.

Making the round of the Chinese Empire, it is apparent that Tibet and Mongolia, for all the resistance that could be made, might be taken by England and Russia respectively whenever they were minded to cross the border. The Chinese could throw out barring columns no further westward than Sze-chuan, no further northward than the Great Wall.

On the frontier of Corea, the Yalu River formerly defined the first line of defense. But this frontier has been moved westward by the Japanese, so that it would be a political impossibility to put men there even were it practically possible. The present line would of necessity be between Shan-hai-kwan and Yung-ping. Perhaps withdrawals from the northern provinces, the viceroys permitting, might admit massing here fifty thousand troops. But this, as well as any other possible line, is entirely unfortified, giving hardly more advantages to the repelling than to the attacking forces. There would be no second line of defense, nothing to fall back upon but the old Tatar Wall of Peking. Beyond this fifty thousand any quota brought from the south would consume a very considerable time, probably a month, even allowing that their semi-independent viceroys did not discreetly hold off altogether.

Further east, at Shan-tung, Germany's railway pierces to the heart of the Confucian province; while from the Chinese military centre in Chi-li there is no corresponding railroad, Chinese-manned, giving them access, were it necessary to repel aggression. The Anamese railways afford the French means of bringing up troops, where China could assemble an army only after weeks of marching. The Burmese frontier of Britain's dominion is similarly vantaged.

The German _Land-Wehr_, while the first armies go to the front, may be called out and mobilized, until the whole manhood of the nation is in arms. Such a body is nonexistent in the Celestial Empire. Like her own lichee nut, once the frail shell of her resistance is broken, the meat is ready for the eating. Considered solely from the military standpoint, aside from reform as such, China is as supine as a huge helpless jelly-fish, with disconnected nerve-ganglia, and not even the rudiments of a backbone.

For the first requirements of national defense, what is necessary? For the north there should be a thoroughly drilled and equipped regular army of at least one hundred and fifty thousand men, with capacity for rapid concentration in the neighborhood of Peking. For the south a standing army of at least fifty thousand men. An intermediate army of fifty thousand more should be available near Hankow, capable of being thrown either way. The Peking-Hankow railway line must have strategic branches to Canton, Shanghai, Yun-nan, and Shan-tung. These must be controlled not by foreigners but by Chinese. There must exist a reserve of, say, five hundred thousand men, at least partially drilled, from which to draw reinforcements. There must be arsenals able to make all the weapons and ammunition for these forces, since foreign nations will continue to command the sea. The sums needed to realize

such a programme must be available, and China must possess the organization and fiscal system for the conduct of a war. From this summary it may be seen that adequate defense requires a measure of increase in her efficiency that is revolutionary. The demand which such measures would make upon any nation is stupendous. How much more would it exact of China, where for its accomplishment every single factor must overthrow the ideas, the principles, the very morals evolved through centuries in the most conservative race of the globe!

At the outset, for the personnel of such a regular army, two hundred and fifty thousand adults must be transformed from stolid, superstitious field-tillers and coolies, never of combative spirit, into courageous, disciplined fighting men. Can this be done? Some, eminently qualified to judge, answer that it can; but Chinese history has not for several thousand years furnished many glorious annals. Where a stark fight is recorded, as at Albazin, or against the Mongol khans in the sixteenth century, the warriors have been Manchus rather than Chinese. Whenever an aggressive nation, be it Hiung-nu or Khitan, Mongol or Manchu, British or Japanese, has gone against the genuine Chinaman, the latter has invariably submitted. It is only when his subjugators, absorbed into the swarming mass of conquered, have degenerated, that the native has been able to rise and drive out his enfeebled oppressor. The Chinese have conquered by time and their birth-rate.

[Illustration: PEKING Where the Allies' main assault was made]

On the other hand, the Chinaman has qualities which, translated into military virtues, should theoretically give him a great initial advantage over any other race. He is comparatively without nerves; he can hold a gun without a tremor for what to a Westerner is an inconceivably long time; he has good eyes and a strong sight; he can be victualed on a few handfuls of rice; he is entirely indifferent as to where or how he lodges; he is sober and reliable; he is a big-bodied man, stronger even, perhaps, than the Japanese; he is docile, obedient, and susceptible to discipline. Indeed, in all that concerns his physical qualities and certain moral superiorities, one could not ask for better raw material. When well led he has at times done very creditably. A generation of such leadership as Yuan Shi Kai's would do not a little toward bringing out what there is latent in this people.

If in the army organization the gap between what is and what should be is so great, how much wider is it in the government organization needed to finance reform. The revenues of China are some $100,000,000. About $36,000,000 are allotted to military purposes. When from this has been deducted the eighteen million-odd which go to the generals of the Red and Green Banners, there is left, theoretically, about $18,000,000 for the real army. Actually there is efficiently applied probably not over $10,000,000. The regular army of Japan--two hundred and twenty-five thousand--takes $40,000,000 effectively expended. China must begin from the very bottom, whereas Japan is simply carrying along. A judicious total expenditure of at least $50,000,000 is needed for China's army. With the additional railway and arsenal programme, and other concomitant work, the demands over and above present outlays would reach around $110,000,000. Add this to the present budget, less the well-spent ten millions, and there is to be reckoned a total budget of at least $200,000,000.

Could China raise such a defense-fund on top of her present hundred-million-dollar budget? Could she cut down on present expenses to help it out? The latter might be considered. Theoretically the wasted army money of the present budget might be saved and applied. Practically the vested interests in the graft are so important as to make it of infinite difficulty. The mere beginning of sinecure-cutting cost the Emperor the actuality of his throne and nearly his head.

The list shows other items of expenditure which cannot be materially economized. The large and growing sum which goes to repay interest, foreign loans, and indemnities, cannot be touched, nor can the $16,000,000 sent to the provinces for their local expenditures. The $8,000,000 for the Peking salaries and palace expenses is a fixture. The modest and well-administered $3,000,000 of the customs expenditures, covering about all the public works that China undertakes,--the lighthouse and coast-patrol allowances, the mails, the interpreters' school,--this cannot be pared. The needed money must come if at all by increase of the receipts. One is driven irresistibly back to the Government's taxing capacity.

The physical possibility of such taxation undoubtedly exists. The per capita revenue which the Government receives from its four hundred million subjects is but twenty-five cents. The American per capita revenue is eight dollars, the Japanese five dollars, the Russian twelve dollars, the Indian--perhaps in conditions the closest parallel to the Chinese--one dollar and a quarter. An extra twenty-five cents would raise the Chinese Government well above all financial difficulties, and still leave the rate far below that of the other great nations of the world.

Looking at the actual mechanism for revenue collection, one is met by difficulties which have rooted themselves deeply into the system. One cannot squeeze any larger proportion of the needed sum than the present $25,000,000 from the Imperial Maritime

Customs. Tariff-rates are fixed by treaty, and the collections, under English direction, are as efficient as they can become. The likin duties on freight during inland transit are such a plague to commerce that, far from being increased, they should be swept away altogether as one of the earliest of reform measures. This $14,000,000 is produced at so heavy a price of fettered and thwarted commerce that added tariff would but aggravate the strangulation without materially increasing income. The opium revenue of $5,000,000 is likewise an item which, for the best interests of China, should disappear from a reformed budget, and the “foreign dirt” from the Celestial domain. In any event opium cannot be made much more productive.

After these eliminations there are left items which bring in $56,000,000. The sources consist principally of the land-tax, the grain-tribute, native customs, and the salt gabelle. The returns from these factors would require to be nearly trebled, if they were relied upon to make up the bulk of the needed total.

The method of collection is a further check to greater income. The existing machinery of fiscal administration operates, roughly, as follows: When the funds begin to run short for the usual expense-accounts, the various executive boards apply to the Board of Revenue. The latter makes a glorified guess at the sum which, considering harvests, rebellions, and other elements, each province might be able to pay. It is thereupon put to the provincial officials, consisting usually of a viceroy, a governor, a treasurer, and a judge, to supply something approximating this sum. The provincial syndicate, through the medium of various intermediate officials, such as the _tao-tai_ and the _fu_-prefect, whose powers are nebulous and overlapping, call upon the eighty-odd county magistrates for an estimated share. The magistrates, _shien-kwan_, called colloquially “father and mother officials,” whose varied functions include rendering justice, keeping the jail, leading the religious processions, and collecting the taxes, send out each his hundred henchmen to get the actual money or grain. Of this hierarchy of officials not one has a salary which would keep his establishment going for a month. Of necessity the laborer must draw his own hire first from the harvest.

Under such a satrap system, by the grace of human nature, each official takes what the traffic will bear, letting pass to the man higher up enough to conciliate his claim and to keep face with Peking. If the penalties which follow deficient generosity to a superior define the maximum contribution, the minimum is fixed by the famine or the rebellion point. With this method in vogue, it is not unreasonable to assume that the amounts gathered in the first instance are about as great as can be wrung from the people. An increase of the Government’s receipts would have to come through shaking down the office-holders for a larger share of their pickings. Such a revenue as a real reform would demand must despoil of vested rights in his livelihood every mandarin, viceroy, _tao-tai_, _fu_-prefect, magistrate, and petty publican in the empire. It might be practicable to commute the likin, or inland octroi dues, for fixed sums by agreement with the _hongs_, or merchant associations. This was done in Li Hung Chang’s province, Kwang-tung, where $2,750,000 was paid in order to get rid of likin dues which netted only $670,000. Enough might be raised by this means to pay the officials at just rates. Then honest collections might reasonably be demanded, and a beginning be made of fiscal reform. But it is apparent from these outlines how long a way China has to travel before her capacity for self-defense is a reality.

The facts are now being comprehended by all classes. From the coast cities, a growing number of young Chinese have been sent to study abroad, mainly in Japan--as many as fifteen thousand in 1907. Returning, these so-called “students” have become the leaders in the boycotts against the United States and Japan. They have engaged actively in propaganda of a patriotic nature, and, more constructively, have translated into their mother tongue hundreds of books on history, economics, and law, including the whole Japanese code, Herbert Spencer, Huxley, Voltaire, Montesquieu, the “Contrat Social” of Rousseau, the works of Henry George and Karl Marx, and many others of the same general nature.

These movements show a widespread public opinion friendly to Chinese regeneration. Various administrative measures have been inaugurated which are yet more promising.

The old method of dividing the Peking Bureau into provincial departments, and letting each of these care for every sort of business from its special province, has been altered. Instead of a bureau having general charge over the salt-tax, the customs, and the appointments of each province, there have been organized ten departments, dealing each with its specialty throughout the entire realm. The five recently-created bureaus--Agriculture, Works and Commerce, Police and Constabulary, Post-Office and Education--tell by their names the centralizing purpose of the new régime. Formerly five hundred clerks attended a department, with office-hours from eleven A.M. to two P.M. including lunch, smoking-time, and due intervals for examining peddlers’ wares. Now a much reduced force is employed, with actual working-hours generally from nine A.M. to four P.M. The foot-binding of children has been prohibited; pressure has been put upon the officials who smoke opium to abandon it, under penalty of dismissal from the service; classical essays as a civil-service examination subject are being given up, and the education of the Chinese youths abroad

is being encouraged. A large number of Japanese officers have been engaged to train the khaki-clad and well-armed Chinese regulars, who have shown excellent aptitude. The Government has bought back practically all foreign railroad concessions, and all the valuable mining concessions except the Kai-ping coal-fields.

Even representative government is well under way. The Dowager Empress's edict of August 27, 1908, by which a nine-year period was set for the devolution of legislative powers to provincial assemblies and a national senate has been justified by remarkable success. The local legislatures, elected under carefully restricted suffrage qualifications, have grappled earnestly with the economic problems of the districts. The senate, of thirty-two members, selected by the Prince Regent from an elected body, has not yet had time to show results, but the calibre of the men in it is encouraging.

China is making a real effort to get abreast of the times. But never was a nation brought more directly before the judgment-bar on the plain test of character. Upon the capacity of the race for private sacrifice and public honesty rests primarily her salvation. Whether China can or cannot rise to the task depends upon her own manhood, and no one can be prophet of the issue; for all estimate of Chinese character is perplexed by that curious Eastern subtlety of contradictions which baffle understanding.

The inability of the Chinese to keep fingers out of the public till is proverbial; yet the very high standard of business integrity is universally conceded.

[Illustration: SUMMER PALACE OF THE EMPEROR]

The quality of Chinese honesty is attributed by some to the local idea of good form, and the obvious mercantile maxim that future credit depends upon present performance. Bourse operators may be scrupulously exact as to obligations which the mere lifting of a finger imposes, while engaged in campaigns diverting to their private speculations the funds of a chain of banks, or looting the values from the minority owners of a street-railway.

Chinese business integrity is said to be due to the fact that her merchants are of the upper class; cowardice in war, to the fact that her soldiers are of the lowest caste. In Japan the condition is exactly reversed: hence the prowess of her Samurai, and the peccability of her clerks--such that Japanese bankers employ Chinamen to handle their money.

Since the Japanese have built up an effective public administration, it is fair to give the Chinese the benefit of faith, and to assume that in time they too will rally to the task, and make a modern state.

With this should come the Trans-Mongolia Railway: opening to the plainsmen of Central Asia a prospect of civilization and advance.

Equally or more important, looking at things broadly, it would give to the world the best of the great Asian trade-routes. Examine a globe and see what, in the shortening of distance, this land-route to Peking signifies. Note the enormous circumnavigations that must be made in going around by India and Suez, and measure then the direct overland route by the Urga Post-Road and the Trans-Siberian Railway.

The bulky freight from the Asian Coast to western Europe will still pay tribute to the sea. To compete with vessel-transportation, which carries a ton from Shanghai to London for seven dollars, the railroads over the 7283 miles from Vladivostok to Paris would have to make a rail-rate of one tenth of a cent per ton-mile; this is impossible when one remembers the average American rate of eight tenths of a cent. But North China, all North Asia, and Europe west of Moscow, are within the railway radius of an Urga-Peking line.

From interior China may be drawn the goods for half a continent. The tea-freight which Russia receives over the long sea-trip to Odessa, or by the trans-shipped Vladivostok route, can be loaded then at Kalgan on the car that goes to Moscow. By it the silks of the Tien-tsin merchants may be rolled through into the freight-yards of St. Petersburg, and the timberless cities of interior China may build with the wood of the Yakutski Oblast forests. By it the dwellers in the valley of the Hoang-ho, "China's Sorrow," may be nourished in their need with the wheat of the Angara Valley; the Manchu mandarins may be clad in the furs from the Yenesei; the ploughshares tempered in Petrovski Zavod break the ancient soil of the Chi-li Province; the silver of the Altai Mountains make the bangles that deck the anklets of the purdah women.

For America the road will open a commercial highway into the very heart of a new and expanding empire. American rails may carry American cars,--those ever moving shuttles which weave the woof of trade. American woolens and felts may protect the Siberians against their Arctic cold, American machinery mine and refine their gold. New England cottons, utilizing the Panama Canal, may

clothe the myriad coolies of interior China. Here is the mail-route of ten days from Paris to Peking, against the thirty-five days needed by the fastest ships. Here is the quickest passenger-route from London to Yokohama. All these potentialities lie as the fallow heritage of the Urga Road, if beyond Kalgan it is given its avenues to China and the sea. It is civilization that must profit when the equilibrium of the East is restored, and over the old Urga Road China is relinked to the West by the trains of the great Asian Railway.
